WBAY, New York, Will Broadcast Personal Messages See Page 16

(Photo by Morris Rosenfeld, New York)

The radio transmitter forming the heart of WBAY, the broadcasting station of the American Telephone and Telegraph Company, is shown in the accompanying photograph. It is located on the upper floor of the company's building, on Walker Street, New York City.

The tubes are mounted in the upper part of the framework of the transmitter (See 9). This location is used because it provides adequate ventilation. The current for heating the filaments is supplied from a constant potential generator. Means must be provided, in the radio operating room, so the radioman in charge can see at once just what power is being used.

1 and 2 indicate the two meters which are the telltales of the direct current flowing. These meters register the amount of current used.

3 indicates the rheostat and the protective devices which cut, in or out, the units of the set.

In order to operate these instruments the necessary electric feed wires must be brought to the panel by conduit pipes. These pipes are indicated by 4. Not only must the electric-power wires be run in a conduit pipe, but the conduit pipe must be grounded, as shown in the photograph. The ground clamp is fastened to the panel by screws. It runs to each pipe where it is grounded. This prevents the high-frequency current that is being generated in the air surrounding the instruments to become affiliated with the low-frequency currents, preventing the generators from being ruined.

The next step is to force the necessary current to the vacuum tubes. Here is the most critical and important stage of the transmitter. This is where the operator must know what the vacuum tubes are doing. The only method employed is the use of meters. These electric meters are somewhat like the meters indicated by 1 and 2.

5 indicates the necessary meters which permit the operator to know how the vacuum tubes are working.

The frequency of the transmitted energy (wave length) is controlled by the value of the inductance in the oscillatory circuit, which includes the antenna. This inductance is adjusted by means of a variometer, indicated by 6. A variable condenser, connected across the plate-coil, controls the plate current through the oscillator tubes. This condenser consists of a variable unit in parallel with two fixed units which may be switched in or out of the circuit. The variable unit is controlled by a knob on front of set 7.

This microstat is far more durable than any ordinary rheostat; is made of better material with greater care.

Order through your dealer or
delivered to any part of U. S.

\$1.40

The microstat takes up less room on the radio board than any other rheostat. Is neat, compact, and particularly designed for those who want the best in radio material. This device is made under the most exacting supervision, and each part is carefully and accurately machined. A template and full instructions in each box, so you can quickly and satisfactorily place the microstat on your set with the greatest ease and neatness.

The exact calibrations of the microstat are due to the gradual entering of two points into the resistance material of our own composition, which gives us exacting and most minute measurement of current to the filament, as the operator brings the two points together or separates them thru the screwed handle.

In the Heart of a Navy Seaplane

THERE is nothing complicated about radio reception. It proved its merits when the "Sampaio Correia," the Brazilian seaplane left New York City on its flight to Brazil. The accompanying photograph gives a splendid view of the radio installation aboard this "ship," and it shows what can be done in a similar way on any heavier-than-air vessel. The receiving-set consists of a tuner and amplifier unit. A fixed antenna is strung between extremities of wings and tail structures. This makes it possible for the pilot to pick up any messages forwarded which will enable him to make such changes in his course as he desires. Weather reports, storm warnings that are broadcasted hourly are of vital importance to the aviator and it is only by radio that he can get them. Seaplanes are also equipped with radio-compass outfits.

(C. Radio Corporation of America.)

Island's
Big
Radio
Station

To the right in the photograph you will see the antenna of WVP on Bedloe's Island, N. Y.

THE radiophone service of the future is possible to everyone who is provided with a suitable receiving-set. All that is necessary is some kind of aerial, which, for this purpose, may be a single wire, elevated 30 feet or more above the ground and running more than 100 feet, if possible. This

will enable the operator to have a receiving-set that will permit him to listen to the broadcasts on 360 meters. With a somewhat longer aerial, it may be possible that we shall employ a longer wave-receiver and utilize the longer waves used in radio. For this purpose we could listen to WVP, the Signal Corps station of the United States Army located at Fort Wood, Bedloe's Island, N. Y. There is nothing more fascinating than listening to a radiophone concert and service. One turns the tuning handle of the receiving set and, finally, when the tubes are lit, one is able to hear the broadcasting. It is well to remember that the radiophone is subject to the noise dreaded by all radio-men: atmospheric disturbances, or static—and, often, QRM. This is not so bad when listening on 1450 meters for WVP. The accompanying photograph shows the towers and aerial of the Fort Wood station.

(C. Underwood & Underwood, N. Y.)

Increasing the Wave Length of a Receiving Set

By George W. May, R. E.

Figure 1—Inductance coil in series with single-circuit receiver, the details of which are fully described in the accompanying article. Drawn by S. Newman

Figure 2—Inductance in series with primary and secondary of an inductive type receiver. Both elements must be loaded to obtain resonance.

Figure 3—Vacuum tube receiver of the inductive type. Primary and secondary have inductance for increase in wave length as well as the tickler coil for regeneration.

WHAT must I do to my set in order to hear the longer wave-lengths? This question is asked by many fans who wish to listen in on stations with a wave length in excess of 600 meters. Although simple as it seems, the principle of loading up must be properly followed out, provided long wave-reception is desired.

On these long waves—such as 1450 meters, which is above the average wave-length of receivers generally used—some means of increasing inductance must be made. The average receiving-set is capable, ordinarily, of operating only over a comparatively narrow band of wave lengths. This should not be considered a great fault, because sets may be made to operate more efficiently over a narrow band of wave-lengths than over a wide band of wave-lengths. Occasionally one wishes to hear stations operating on the higher wave-lengths—higher than those afforded by the tuning-coil gear on one's

set. In all cases, the range of wave-lengths of the receiving set is increased to higher waves by means of the loading coil, or inductance. This means that more inductance must be added to the inductance already in the set. This instrument may take a number of forms such as tuning coils or honey-comb coils.

It is known that there are two circuits, namely: single- and double-circuit receivers. If vacuum tubes are employed, there also may be regeneration in both cases. In the single-circuit short-wave receiving sets—usually made up of a tuning coil and variable condenser in series with the aerial and the ground—have the crystal detector and telephones in shunt to the coil. Now, if longer waves are desired, simply add another coil in series with the aerial and ground. Remember, this coil is in series with the coil in the set.

There must be a sufficient number

of turns depending upon the maximum inductance of the other coil in the set. Remove the condenser in series and place it in shunt to both coils. The detector remains the same, whether crystal or vacuum tube.

When a two-circuit receiver is used, another coil must be connected in series with the secondary in order to balance the two circuits. If a loose-coupler is in use, a moderate amount of loading may be used in the primary circuit without any in the secondary as secondaries of this type instruments are usually wound with more wire to compensate for the slight loading.

If the circuit in use employs a vacuum tube as a means of regeneration, or in conjunction with a tickler coil, the question of loading up for the longer waves is a little more difficult as in the double-circuit receiving-set we must load up the three coils, namely: primary, secondary, and tickler coil.

Gave Him the "Double Throw"

By Jack Turner

Radio Editor, "The Age-Herald," Birmingham, Ala.

I SAW Ray D. Owe downtown the other night, and with him was Anne Tenna. I had told Ray that I would like to "meter," so he introduced me and I asked her if she wouldn't like to have a "feed, back" around the corner, and she said that it would just "tickler" to death.

When we went in, she took off her hat and I saw that she had her hair done up in "short," "continuous waves," and wore a "switch" or two. She said she just "came in" town. I asked her what "station," and she replied, "The 'Terminal'."

I said to her, "You are the 'cat's whisker'—you have eyes like 'crystal'—I 'solder' like you." When I told her that I was going to kill a mosquito that kept buzzing around my head, she said, "kilowatt?"

Anne ordered so much that I thought she would "choke," and when the

We have not as yet found out even an infinitesimal part of the many things radio will do for mankind.—Prof. J. A. Fleming

waiter brought a cake that was full of "currents," I broke my "plate."

There were many people there "antenna" them were dancing. I asked Anne for a dance and she didn't offer any "resistance;" but we didn't have much "selectivity" as I could only do the "one step." She told me that I danced like an "amateur." Once I hit the "ground" when I did a "loop." But she couldn't dance much "ether." After dancing with me once, she would re"fuse" if I asked her for an encore.

While I was talking to her, she told me that I was a "loud speaker" and that I "broadcast" everything I said. When the waiter "brought in" the check, I told him to "charge" it.

I asked her, "'Wire' you in such a hurry?" She answered: "I must go 'ohm' because I don't want to get 'insulate.'"

The Importance of the Variometer to a Receiving Set

By Donald Van Wyck

Figure 1. The use of the variometer as a variable inductance in the inductive-coupled receiving-set. Drawn by S. Newman.

A SIMPLE means of tuning-in a radio set is afforded by the variometer. This piece of apparatus, widely known, is one of the instruments that tend to make up a certain type of regenerative set. In its simplest form it is quite easy to make and parts for its construction may be easily purchased and assembled.

A variometer is particularly adapted for the construction of radiotelephone receiving sets. They effectively cover a wave-length range from 150 meters to about 600 meters. A variometer is built up of two spherical coils. One which revolves, is termed the rotor; the other, which remains stationary, the stator. The rotor, or secondary coil, turns about its axis inside the stationary coil, or stator, which acts as the primary. The variometer, as its name signifies, is a variable type of inductance, but it is different from tapped coils, or coils with sliders, in this respect: there is no variation in the length of wire. In the inductance of a variometer, the variation is accomplished by the rotor revolving inside the stator, or primary. This proves that the elimination of multiple point, or tapped switches, permits variation without any break in the circuit whatsoever. With this important feature, the variometer is adapted for the vacuum-tube work, since switches or taps are likely to leave a break in the circuit when the set is being tuned.

A variometer with a rotor shaped like a ball, is known as the ball type; another type consists of two cylindrical tubes, one rotating within the other. This type variometer does not have a minimum or as high a maximum inductance as the ball type. The best variometers have a minimum clearance between the rotor and the stator, and both coils have the same inductance. It may be then said that a variometer is a tuning coil in which the primary coil is fixed and the secondary coil

movable and revolving at right angles to the primary. One end of the primary is connected to one end of the secondary. It has no sliding contacts or other means of varying the inductance of the primary and secondary coils, but tuning is accomplished solely by varying the coupling between them. This is what happens in the variometer when the tuning adjustments are made by turning the variometer dial.

When a current flows through the coil—in this case the stator—a mag-

Figure 2. The use of the variometer as a direct-coupled tuning transformer, well adapted for short-wave reception. Drawn by S. Newman.

netic field is set up about the field surrounding the wires. When the current in the coil is varied, there will be a corresponding variation in the magnetic field. If another coil, the rotor, is placed in proximity, the changing magnetic field will induce, or set up, a voltage in the secondary coil. Connected to the second coil—or, as it is known the secondary—is a detecting

Argentine Fans to Build American Sets

ARGENTINE radio fans soon will be building receiving sets along the lines of the specifications issued by the United States Bureau of Standards. Believing in the development of radio, especially in the efforts of the United States Bureau of Standards to simplify and standardize home-made or assembled sets, the Argentine Embassy has just completed the translation of the Bureau of Standards illustrated reports on building simple and two-circuit radio receiving sets at home. These pamphlets, which were popular in this country, are expected to be equally as popular in the Argentine now that it is in Spanish.

Radio Catches Everything

IN a radio broadcasting studio the absence of a visible audience often makes a singer forget that several thousand people may be listening to him. Such was the case with a soloist at one of the local stations recently. At the end of a fine tenor solo, listeners heard the singer say, "How do you shut this — thing off, anyhow?"

Figure 3. View of variometer giving a larger range of inductance variation than some of the other types of variometer. This is known as the ball type. Drawn by S. Newman.

device such as a telephone receiver, which records the change of current. The induction of current from the primary to the secondary is termed mutual induction.

In two of the circuits illustrated, the use of the variometer in Figure 1 is shown as a variable antenna-inductance; while in Figure 2, the use of the variometer as a direct-coupled tuning transformer is shown. This circuit is particularly suited for the shorter wave-lengths, such as 200 to 500 meters. A large range of wave-length variation cannot be obtained from a variometer when used as the sole tuning-element unless it is made very large and wound with a large number of turns of wire. The circuit shown in Figure 2 has been used for long waves using a large variometer and a vacuum-tube detector. The manipulation of the variometer is very simple.

Figure 3 shows a variometer used in a regenerative vacuum-tube set. One variometer is placed in the grid and the other in the plate circuit. Any circuit that gives regeneration is called a feed-back circuit, from the fact that oscillating energy is fed back from the plate circuit to the grid circuits. There are several feed-back circuits. The two most commonly used in radio receivers are the "tickler circuit" and the tuned plate, regeneration being accomplished by employing the variometers.

In this case, the inherent capacitance between the grid and plate is relied on for coupling. The choice among different forms of feed-back circuit lies in convenience, design, and use.

Successful Stunts of an Amateur Radioist

By C. F. Rye

Adjusting Diaphragms on Receivers

HAVING different makes of receivers on hand, including some cheap ones, I tried to make some of the low-priced low-ohm receivers more sensitive. I was successful with all.

Looking them over, I noticed that they varied in length from the magnet to the diaphragm, and as the more expensive ones were of standard length and much closer, I tried to duplicate them by cutting down the outside edge of the rubber on which the diaphragm rests, thus permitting the diaphragm to come closer to the magnet. By so doing, I expected increased action due to a stronger magnetic field.

The cutting of the rubber was easily accomplished by laying fine sandpaper on a smooth table, and gently rubbing the body of the receiver over the paper.

If you happen to take off too much, you can place paper washers under the diaphragm to raise it from the magnet.

You had better use a straight-edge rule to see how far the magnet is from the diaphragm as it may be too close and be the direct cause of a tinny sound.

You may wonder why the receivers on a head set do not sound alike—one

will be louder than the other. Try them with a straight-edge rule and see if the diaphragm of one is not in a stronger magnetic field than the other.

If so, try to bring the weaker up to the stronger, either by shimming with paper, or removing the bearing portion of the body where the diaphragm rests on it.

I have made a big improvement in my receivers of cheaper make by the method I have here explained. Many of the receivers have metal bodies instead of rubber. The only difference is that the metal takes more rubbing, but the result is the same.

* * *

Using Mercury on Galena

AFTER looking over my crystal set to see if I could improve on any of the connections in order to help the weak current on its way, I remembered that in only a few places was the crystal sensitive.

The thought naturally came to me: How about the places where the crystal rests in the metal cup? Are they sensitive?

Well, to eliminate doubt, so far as possible, I used some cold solder and a drop of quicksilver, or mercury, as a bed in the cup in which to lay my crystal.

The mercury dissolved the solder

and made a thick mixture which gradually hardened and made a metal contact all the way through, improving the strength of signals.

I used mercury in a similar way on a piece that was mounted when I bought it, and this piece also was greatly improved.

My purpose in doing this was to overcome the evil which often occurs in mounting galena—overheated metal in which the galena is placed. Such overheating causes a thin coat, or film, to gather on the outside of the galena.

Later, I cleaned other parts in my hook-up where it was impractical to solder, and gave it a coating of quicksilver, or mercury. I can assure you this operation did no harm.

* * *

Disconnecting a Soldered Joint Cold

IN my desire to secure the very best results from my set and eliminate all noises, I had to solder my joints. This worked well until I wanted to change my connections, as illustrated in a magazine. Then I had to think, as some of the joints were in places where I could not heat them without damaging my set.

After trying to disconnect the joints I used mercury, or quicksilver; and all that was needed was to clean a place on the solder and apply a little mercury to the cleaned spot.

In a little while, the joint was free and ready for a good connection to any other place, as it had a mercury coat on it that helped to make a good connection—just as a wet hand makes an electric connection.

In this case, no solder whatsoever was needed; yet all the good qualities of a soldered joint was accomplished with excellent results.

* * *

Two Aerials Instead of a Ground

MANY amateurs have a poor chance to make a good ground. My best results have been secured without any ground—with less trouble even than digging a hole to bury copper wire.

My plan is this: I set up another aerial and ran my ground connection up to it. My signals—on a crystal set—were loud enough to be heard a hundred feet away with the aid of a horn.

I have a good ground to the water-main, but I prefer my second aerial.

My two-aerial plan may be accomplished by using one of the wires of a double-wire aerial.

Seen at London's First Radio Show

(C. Central News Photo Service)

Radio on motor cars adds to their luxury! This was shown at the First Radio Exhibit held in London. In the ancient, venerable halls of Westminster, modernity held sway. A motor box was fitted up with a receiving set, as seen in the photograph. All you see is the receiving apparatus safely ensconced below the back seat and a bright parasol resting casually in front. The parasol, on further investigation, is a loop aerial, by the aid of which one may ride out to the country and enjoy life. Of course, tea was served at this British radio show, for tea is a necessary element of every British function. This show was the first held in the British metropolis and was largely attended.

Employing Jacks with a Two-Stage Amplifying Receiver

By Fred. Chas. Ehlert

Schematic diagram of a regenerative set, employing variometers as means of regeneration. Jacks are utilized in the stages, which enable the radio listener to use as many stages as he desires. The grid condenser shown in the circuit of the second stage may be left in or out. This is to be considered by experimentation. Suggested by Fred. Chas. Ehlert. Drawn by S. Newman.

TO many experimenters, a two-stage amplifying receiver represents a more difficult problem than it really is. However, it raises important points which cannot be overlooked. The accompanying circuit is a most efficient outfit employing jacks. It is a circuit no amateur should overlook. Each and every part is shown. It may be assembled in an efficient way. It will not tax the financial resources of the average radioman. If experimenters have the material handy, I would suggest that this hook-up be put to the test. One thing that must not be overlooked, however, is the wiring. If leads are run back and forth over the set,

there is sure to be trouble from "howling" because of the feed-back effects between the grid and plate circuits of the various tubes. In some equipped sets elaborate precautions have been taken, with grounded shields between the steps.

Practically all amplifying sets are equipped with jacks. Therefore, I have included these jacks in this circuit. The detector jack is of the double-circuit construction. The first stage is, also, that of a double-circuit jack; in the last stage, an open single-jack is employed. Where it is necessary to run wires close together, slip some spaghetti tubing over them.

When mounting the transformers

I suggest that this be done at right angles to each other. If all my suggestions are carefully followed, no tube noises—such as howling—should be experienced. The detector plate-circuit should have, approximately from 18 volts to 22 volts, while the amplifying plate-circuits should range about 45 volts plate-current. A 6-volt storage battery will be sufficient to light the three tubes, but it is suggested that the amateur get a large ampere-hour battery from 80 to 100 ampere-hour capacity. This will permit batteries to furnish necessary power to the tubes, for a long time, without the troublesome necessity of placing them on charge.

This Discovery May Eliminate the "Catwhisker"

By E. Farig, Ph.D.

BY means of high pressure, and at a temperature of 1600 degrees Fahrenheit, or 1593 degrees centigrade for four hours, metals of a low-melting point (850 degrees Fahrenheit) lose all their original characteristics. They become infusible, cascatic, in form of crystals—hard, brittle, sparkling all over, and have radio-crystal rectifying properties. Pieces tested on a 300-meter wavelength, recorded speech and music perfectly—no screeching—and eliminated the tiresome catwhisker hunt for a

sensitive spot. Tests will be made with alloys to insure a uniform though sensitive rectification.

This same discovery was tested, taking the place of lead batteries, elements in storage and under these tests gave very promising results. This crude substance "metaloid," is a new product not yet known to science. The treatment for rectifying is simple and the mounting of these crystals offers no difficulties.

The best rectification quality I have found, is a passage of current of from .02 to .04 M-A; whereas 5 M-A is of no use. I think this discovery is of sufficient importance to let the industry know what is being done by research engineers.

Why it is Possible to Operate with a Vacuum Tube

By John Kent

(C. Ewing Galloway, N. Y.)

Type of Vacuum Tubes as generators for the delivery of electromagnetic waves for radio transmission.

RADIO frequencies lower than 20,000 are seldom used. If they were impressed on telephone receivers, the note—even if the receivers would respond—would be inaudible since the ear will not record frequencies much above 15,000 cycles. The problem is to reduce the frequency used in radio so it will not be inaudible in telephone receivers. This is accomplished by the detector, an instrument which groups a number of cycles of high-frequency current and delivers them as one cycle of low-frequency audible in the telephone receiver. Detectors are made in many shapes and forms. One of the best detectors ever invented is the vacuum tube. This instrument was perfected about 1910. Since that time, its use has been increasing daily.

The vacuum tube consists of a evacuated vessel somewhat similar in size and construction to a small incandescent-lamp. Instead of two connections—made in the case of the electric lamp—

the vacuum tube, or, more properly, the electron tube, has four connections. Two serve the same purpose as those of the incandescent lamp; namely, to light the filament. The other two connections lead to two new elements known as the grid and the plate. There are, therefore, three elements in the vacuum tube—filament, grid, and plate. These elements are arranged with the filament in the center; the grid on the outside of the filament and the plate outside the grid.

The filament consists of a tungsten wire; the grid of a small coil, or mesh of wires; and the plate of a thin sheet of metal. The tube operates as follows: A 6-volt battery is connected to the filament which, when lighted, shoots off small particles of electricity in every direction. A battery of 22 volts is connected with the positive side to the plate and the negative side to the filament. When the battery is connected, the small particles of electricity which are shot off from the filament,

and which are negative in character, are attracted to the positive plate. Therefore, a current flows between the filament and the plate.

If a third battery, or an alternating current such as that due to a signal, is connected to the grid—and the voltage of the grid is changed—it will be found that the current flowing in the circuit formed by the plate and filament, will vary in exactly the same manner. The variation, however, will be much greater than the small voltage impressed on the grid would warrant. The current will increase when the grid is positive, and decrease when the grid is negative. The fact that the plate current is so much greater than the grid voltage would warrant, shows that the vacuum tube is acting as an amplifier. This is a valuable property, one which makes the vacuum tube successful in its application to radio. The same property, by a slight alteration of the circuit, may be used to make a vacuum tube and an efficient detector. The use of the amplifying property is familiar in the construction of numerous two-stage amplifiers now on the market. Amplifications of many hundreds and, frequently, thousands of times are possible. The plate current is sufficient to operate a pair of telephones, or ear pieces.

(Photo by Paul Thompson)

The 5-watt Transmitting Tube now used by the United States Navy.

Radio Big Help to Airship C-2 on Western Trip

By Carl H. Butman

WASHINGTON, D. C.—Radio aided the United States Army airship C-2, on the westward leg of her transcontinental trip. During the sixty-hour cruise, hundreds of miles of which were traversed in darkness, radio was always available to lend a guiding hand when any doubt as to the position of the airship existed on what was the first transcontinental airship cruise.

All Army airships and airplanes are equipped with the latest radio apparatus. In many instances, radio has informed the pilots as to location, course, or weather. In the event of an accident or trouble, it has been the means of bringing aid.

The first thousand miles of the western trip was made in approximately twenty hours, flying time, Major Strauss, the commander, reported from Belleville, Illinois. All along her westward route from Norfolk over Akron, Belleville, Fort Sill, San Antonio, El Paso, Yuma, to Arcadia, California, Captain G. A. McEntire, the radio officer, kept in touch with Army, weather bureau, and private radio stations which advised him regarding the meteorological conditions to the westward. Radio will again guide C-2 on her return trip to Langley Field, Virginia, this week.

The radio equipment of the C-2 consists of a modified SCR-67-A radio telephone and telegraph vacuum-tube set, with a sending radius of about ten miles for the phone circuit and forty miles for the telegraph. The transmitting wave used was 480 metres, but messages on nearly all wave lengths were receivable. In the present installation batteries are used in sending, but the radio experts of the Army Air Service have been experimenting on a generator geared to one of the driving engines, which will give these radio sets more power. The antenna is a single wire trailed below the airship and is about 100 feet in length.

The C-2 will remain at Ross Field for several days in order to afford her crew a needed rest and give the people on the Pacific Coast an opportunity to witness several exhibition flights. After some slight overhauling she will return to Langley Field over the same route, Major General Patrick, chief of the Army Air Service, stated a few days ago. This transcontinental flight was intended merely to point the way for flights across this route for larger airships. The southern route was

chosen because hangar facilities and landing crews were available at the several stations en route.

Arrangements were made whereby most of the flight of the C-2 across the United States was done at night. Airships are in their element in night flying, as atmospheric conditions are much calmer than during the day, less hydrogen gas is lost through expansion and better static equilibrium is main-

tained. Night flying in airships is a reasonably safe proposition, for even should motor trouble develop, repairs can be made while the ship is drifting in the air, no forced landing being necessary.

It was during the night trips that the radio equipment proved most valuable as well as a means of entertaining the crew, who frequently listened in to radio concerts while en route.

M. R. Brennan, Superintendent of the N. Y. Police Telegraph Bureau at WLAW Station

(C. International News Reel Photo.)

The interior of the radio broadcasting-station of the New York Police Department has been assigned the call letters, WLAW. M. R. Brennan, Superintendent of the Police Telegraph Bureau, is photographed at the transmitting apparatus. Tubes are used as means of power transmission. The filament current-control of each vacuum tube requires about 6.25 amperes. Current for lighting the filaments is supplied from a constant-current generator. The modulation system used with this equipment, in connection with the Western Electric tubes, insures the highest efficiency in clearly reproducing speech and music. It has complete and perfect modulation. In this photograph the transmitting gear is at the right. It is better known as the panel-control board. On this board all adjustments of power are made. The horn is a Western Electric power amplifier-unit, used as a loud-speaker in connection with the receiving set. To the left of the horn is the receiving set. The little round object lying on the table is the transmitter. Through this the broadcasting is started. This transmitter, in turn, sends the spoken words to the main transmitter, where the vacuum tubes perform the necessary work. To obtain the best results, the magnitude of the feeble currents produced by the microphone must be increased many times before they are impressed on the radio transmitter. For this purpose, an input amplifier provides the necessary amplification. This consists of a three-stage amplifier so mounted that all the controls of the amplifier are accessible. Current to operate the microphone is supplied by an 18-volt storage battery and is regulated by a rheostat on the input-amplifier panel.

The Passing of Poldhu—MBD

Famous Cornwall Station where Marconi First Used Transatlantic Radio Had a Romantic History

By *Arthur G. Shirt*

AS science progresses, instrument after instrument go their silent way to the junk-heap, forgotten by all except a few, whose duty it is to classify and preserve the remembrance of radio gear that has come and gone. There is little or no sentiment attached to this process. Like obsolete theories, the wireless antiques are of no interest. On the other hand, when a unit of a great system of communication passes into the discard, such as the famous MBD, at Poldhu, Cornwall, Wales, it is only too proper that due respect should be paid to its memory. Poldhu, now abandoned in favor of the station at Clifden, Ireland, has played its part in the building up of the immense world-circling Marconi system of radio communication. It has stood the test, and from

the night of December 12, 1901, when the first weak signals were pushed across the Atlantic to the day, in September, 1922, when the station was closed to traffic, Poldhu has maintained its end of the system.

The story of the first transatlantic signals weaves itself around the Poldhu station. Marconi was in England at the time, conducting experiments before the officials of the postoffice department, and demonstrating, with the rapidly increasing range of his crude instruments, that the limit of radio signalling was practically unlimited. But men who called themselves practical—men opposed to Marconi, who was supposed to be visionary,—said that the curvature of the earth would prevent transmission to any great distance. They were

judging the capabilities of this new force which follows the contour of the earth by the conduct of other systems of signalling, such as the heliograph and other sight devices. Marconi, not as well acquainted with wireless phenomena then as he is to-day, thought differently; but up to that time, the distances covered proved neither one thing nor the other. Naturally he was particularly anxious to establish transatlantic records, so that for once and all this question of limiting the scope of radio waves should be settled. For him, it meant a matter of gaining the backing of those who withheld their valued support unless this particular controversy was cleared up.

So eager was Marconi to prove that curvature of the earth would not interfere with the progress of electromagnetic waves, that he started on the station at Poldhu at a time when his instruments had accomplished the record of only thirty-six miles! What greater tribute could there be to Marconi's faith in the possibility of his invention? At the same time, a similar high-powered station was commenced on Cape Cod, which was to be the American side of the great test. Marconi knew that to produce electro-magnetic waves of a force sufficient to bridge the Atlantic, he must have instruments far in advance of what he then possessed. He couldn't have instruments that differed to any great extent, for what he had already evolved represented the peak of radio progress; but he could and he would have them larger and more powerful in every respect. So the layout of the station at Poldhu, as it was when the signals were hurled across the Atlantic, were no different in theory than the amateur spark-coil outfit of to-day, with a transformer, condenser, and inductance coil. But there was a generating plant consisting of an alternator capable of an output of about twenty kilowatts, which through suitable transformers, charged a condenser having a glass dielectric of great strength.

The aerial at Poldhu consisted of fifty almost vertical wires, arranged in the vertical fan style, and supported at the upper end by a wire

Radio Set Just Fits Man's Hand

(G. Underwood & Underwood, N. Y.)

So many amateurs have been making miniature radio-sets that we are showing in the accompanying illustration an unusually small one. It fits into the palm of the hand. There is no question that it works but no records are claimed for receiving long distance with it. Remember it's only a miniature set, but it works.

An Amateur, to Get a License, Must Read Ten Words a Minute

(Republished by General Request)

INTERNATIONAL MORSE CODE AND CONVENTIONAL SIGNALS

- 1. A dash is equal to three dots.
- 2. The space between parts of the same letter is equal to one dot.
- 3. The space between two letters is equal to three dots.
- 4. The space between two words is equal to five dots.

(Continued from preceding page) stretched between two masts. The masts were 150 feet high, and 200 feet apart. As first erected, they were not strong enough to withstand the gales of a Cornwall winter, and on September 18, 1901, were blown down during a raging storm. Work was again started immediately, in an endeavor to have the Poldhu station and the Cape Cod station ready at about the same time. But a further delay came in the form of a storm on the American coast, which wrecked the masts at Cape Cod. This was in November of the same fatal year, and Marconi's discouragement was extreme. But with a determination that characterized his actions from the very start, he completed the reconstruction work at Poldhu, and then journeyed across the Atlantic with a few assistants and a makeshift receiving set, which he installed in a rough building on the cold shore of St. John's, Newfoundland. He could build no masts, and so sent his aerial aloft by the means of kites, which made the stupendous task he was then engaged in doubly hard. The variation of the wind produced constant changes in the angle and the altitude of the aerial, so that capacity and period of electrical resonance was never the same, making it almost impossible for Marconi, tuning with the temporary instruments below, to remain on any one wave length for any period of time.

On the night of December 11, all was ready. The operators at Poldhu had been instructed to begin sending the test signal—which was the three dots of the letter S—on and after December 11, keeping a steady transmission of that letter for ten minutes and then resting five minutes. When Marconi first listened in at the appointed time, he knew that so far as it was possible to depend on human co-operation, that Poldhu was working and periodically directing her signals towards the anxious inventor in Newfoundland. Across the ocean! Could it be done? Some of the greatest scientists in the world had said that the feat was impossible! But as in the case of the amateur trials, just twenty years later, the momentary failure was no indication of what was to follow. Marconi listened all the night of the 11th, and heard nothing. The day of the 12th was spent in correcting the receiving instruments so that they responded to Marconi's ideas as to what should obviate last night's difficulties, and in the evening of the 12th, to the overjoyment of Marconi, the monotone signals from Poldhu station were

heard in Newfoundland. They were faint, of course—dot, dot, dot # #, dot, dot, dot # with a few omissions when the wind got to playing havoc with the fixed capacities of the aerial system. But they were signals! The impossible had been achieved! The Atlantic had been bridged! That accomplished, Marconi could bid for all the support in the world, confident that the radio waves he employed were capable

of something revolutionary in the way of communication. Such is the story of Poldhu—of its building and of its mission. From that day, when its fan aerial was the object of much wonder and speculation, to this, when its arrangements are antedated and its presence in the chain of Marconi stations no longer needed, it has made wireless history. Now it passes forever from our view.

The Radio Primer

A Weekly A. B. C. of Radio for the Beginner, in which Elementary Facts and Principles Are Fully and Tersely Explained and all Words and Terms Used by Amateurs and Experts Defined

By Lynn Brooks

WHAT is a circuit? What are the different parts and what do they represent? Are all circuits illustrated alike?

The accompanying circuit is a good example. It shows the tuner up to but not including the detector circuit. It is a desirable circuit for tube detectors. It is a circuit which may be found in any form of publication. A is the aerial; B the primary switch-handle. C is the tapped primary of the primary

Schematic diagram showing the tapped primary and the secondary of any loose-coupler or vario-coupler. Whenever this diagram is shown it represents the parts explained herewith.

coil marked D. E is the secondary coil. F shows how the coupling of the magnetic waves are induced into the secondary. G is the ground connection. H is the variable condenser in shunt to the secondary of the tuner. I is the grid condenser. J is the grid leak. Usually the grid condenser and leak come together. The grid leak is drawn in either position as shown in the diagram by letter J.

* * *

How can the primary winding of a loose coupler, or vario-coupler, be determined when using a variable condenser? When drawn in a circuit does it always appear this way?

A schematic diagram is herewith published with the variable condenser in series with the primary of the vario-coupler, or loose coupler. This is often termed a tuned circuit. The inductance of the coil is varied by cutting in or out of the circuit a number of turns of wire at a time. The variable condenser consists of two sets of plates—one being stationary and the

other movable. By rotating the plates, we vary the electrical capacity of the condenser. This tuned circuit will re-

This diagram shows the variable contact on the primary which makes it possible to increase or decrease inductance in the primary circuit. A variable condenser is also inserted in series with this primary inductance.

spond to a number of wave lengths at the same time; or, in other words, it will tune broadly.

* * *

Is there any other method used that will answer the purpose of the slider principle?

This has been overcome by making taps on the winding. Wires are soldered on these taps and then brought out to the front of the panel on switch points and a switch handle. The ac-

A tapped primary is illustrated in this manner. It may be seen that if the switch handle is moved, inductance of that coil will be increased or decreased according to the way it is moved.

companying sketch shows how the taps are brought from the primary winding to the handle.

* * *

In using a vario-coupler, or loose coupler, with a variable condenser in shunt to the primary, how should this appear in a diagram? Does it look the same in every illustration?

When using a vario-coupler, or loose coupler, where two windings are employed—such as primary and secondary—the accompanying sketch will show how it is always illustrated. Here the secondary is in shunt to the primary winding, while the arrow shows that the coupler is variable to the principle

When this diagram appears it means that the variable condenser is placed in shunt to the primary of the loose coupler or variocoupler. The arrow drawn through the primary and secondary means that the coils are variable.

of coupling. The secondary coil is usually arranged so that the magnetic field may occupy the same space as the field of the primary coil, or may be varied in position so that it occupies only a part, or none, of the same space. This is called the varying of the coupling between the coils. A is the aerial. B is the primary-coil tap. C is the primary coil. F is the secondary coil. H is the primary condenser in shunt. E is the coupling. D, ground.

In summing up in regard to the diagrams published on this page, symbols are drawn the same in all circuits no matter where such circuits are printed. I would advise every radio amateur or experimenter unfamiliar with such diagrams, or symbols, to study them carefully so that he may readily and easily understand any hook-ups that may appear in radio literature.

Radiograms

Latest Important News of Radio Garnered from the World Over, and Reduced to Short Wave-Lengths for the Busy Reader.

RADIO will be one of the most efficient means of capturing fugitive criminals, says Richard E. Enright, police commissioner of New York City. Mr. Enright made this important statement in an address before the conference of American and Foreign Police Chiefs last week. He added that in a year's time most of his department's out-of-town business will be carried on by radio. In a few years, the police of all parts of America will be in touch by radio, making it possible to co-operate in the apprehension of criminals on a scale heretofore impossible. The days of the guilty are numbered.

An average of 2,500 radio messages a day are handled during each five-day trip across the Atlantic, by the radio operators of the Cunarder "Majestic."

Under the auspices of the Australian government another very large radio station is to be erected near Sydney, its cost to be more than \$5,000,000 and its operation to be conducted by the Amalgamated Wireless, an organization springing from the Marconi Wireless Telegraph Company.

Sweden awarded the contract for equipping her new powerful radio station, to be erected forty miles south of Gothenburg, to the Radio Corporation of America in spite of a lower bid from the German Telefunken Company. The reason was that the American company offered better terms of payment.

The amount of the equipment contract is \$432,500, one-third cash and the balance from future receipts without interest charges. The total cost of the station will be about \$1,300,000.

The first American singer to have his voice broadcast by European radio telephones is Charles Hubbard, a tenor born in Auburn, N. Y. He sent out several numbers from the Eiffel Tower station which has a wave length of 1,760 meters.

The Virgin Islands will install radio apparatus for broadcasting official information and entertainment, according to Adolph Sixto, delegate from St. Thomas. Recently he visited Washington officially, and called at the White House, where he told the reporters that, as a member of the Manufacturers' Commercial Association of the Islands, he was hoping to introduce radio broadcasting as soon as suitable equipment could be secured for sending and receiving.

Rear Admiral H. J. Zeigemeier, director of Naval Communications, who has been designated to represent the Navy at the First Pan-Pacific Commercial Conference, at Honolulu, October 25 to 31, will speak there on communication and transportation, giving special attention to a survey of the present cable and radio activities. He will discuss the establishment of lower special rates, fixing responsibility and granting improved facilities for the press.

New vacuum-tube transmitters are being installed on the submarines of the U. S. Navy. Tests on submarines have been very satisfactory, according to naval experts. The set makes use of equipment already in the hands of the Navy, with some additional material necessary to modernize it. Tests show daytime ranges of from 150 to 250 miles while a submarine was on the surface. It is claimed by experts that it is possible for the submarine to operate its radio while submerged.

WLAW, broadcasting station of the New York City Police Department, although in operation less than two weeks, has been reported from points in New Jersey as coming in so strong and clear-cut that its modulation is a distinct improvement over other stations in the metropolitan district.

Three other cities besides New York are applying radio extensively to aid their police systems in suppressing crime. They are Denver, Col.; Dayton, Ohio; and Chicago.

When William Gibbs McAdoo, former Secretary of the Treasury, and a party of his friends, including George E. Hill, of Rigby, Idaho, electrical dealer, started down the Snake River on a fishing and hunting trip, recently, the raft on which they were carried was equipped with a Crosley Harko Senior and two-step amplifier, used in connection with a loud-speaker. Mr. McAdoo is an ardent radio fan, and has expressed a determination to take a receiving set with him every time he enters territory in which there are no facilities of obtaining news.

Just over the crest of the Kaiser Range in the High Sierras, at an altitude of nearly 10,000 feet, the Southern California Edison Company is operating three continuous-wave radio stations at the highest altitude in which radio communication ever has been installed. Radio communication is being used by the company for the direction of practically all the construction work under way by its tunnel workers, who are a part of an army of 4,500 employees engaged in the company's enormous water power electric development in the mountains of Northeastern Fresno County, on what is known as their Big Creek-San Joaquin River development program, which will bring into service 125,000 horsepower of new electric energy next year.

The Troy Polytechnic broadcasting station was made possible through a large gift from Washington A. Roebing, the late Charles G. Roebing, and John A. Roebing, of the John A. Roebing Sons' Company, Trenton, New Jersey, all graduates of the Institute and famous as the builders of the Brooklyn Bridge. The equipment was installed during the summer months under the supervision of the professors and instructors of the Department of Electrical Engineering, in the Russell Sage Laboratory, erected in 1906 with a part of the million-dollar gift from Mrs. Russell Sage in memory of her husband, who was one of the Trustees of the Institute.

Quotations Received by Radio!

Latest Important Radio News

THE Federal Telegraph Company of Delaware is soon to be launched to take over the \$13,000,000 contract with the Chinese government, recently secured by the Federal Telegraph Company of California. Owen D. Young, president of the General Electric Company, will be chairman of the board, and R. P. Schwerin, head of the California corporation, will be president. The new company will be capitalised at \$9,500,000, divided into \$3,500,000 preferred stock and \$6,000,000 common. Profits from the Chinese contract are estimated at \$6,500,000, in addition to a percentage of the net earnings of the stations for a long term of years.

Notice of a 10 per cent. increase in wages, effective October 1, has been posted in all the larger copper mining camps in Arizona. Companies granting the increase include the Phelps Dodge Corporation, the Calumet & Arizona, Miami Copper, Inspiration, Old Dominion, New Cornelia, United Verde, Ray Consolidated and others. This increase is due very largely to the demand being made by radio manufacturers for copper.

A prominent radio manufacturer notifies us that, according to his estimate, over one hundred million dollars' worth of radio apparatus will be sold this winter.

United States Government experts report that high frequency waves from radio broadcasting stations have caused vegetation to take on a

larger growth and reach maturity sooner than under ordinary conditions.

Lee de Forest, the eminent radiotrician, arrived from Europe on the "Berengaria," last week. He brought with him his latest radio invention, the phonofilm, by which he will reproduce speech in moving pictures.

Radio has been utilized to intercept rum runners on the high seas. According to the "Times," New York, a ship ostensibly bound from New York for Greece was halted by the authorities after radio had notified them of her position and cargo.

The aerial for the new broadcasting station on the Municipal Building, New York, is in place.

American radio exports during July totaled 225,475 pounds of apparatus, valued at \$385,861, which shows that some American exporters are taking advantage of trade opportunities.

Radio Success in Bahamas

About a year ago, the Bahaman Government purchased three radio transmitting sets from the United States Shipping Board and put them in operation with such successful results that three more sets have been purchased for inter-island communication. The equipment is of the 1-kw spark type such as is used on Shipping Board vessels. It gives excellent communication between the islands of the group.

13 More Broadcasters

THIRTEEN limited commercial broadcasting stations were licensed by the Department of Commerce during the week ending September 16, as follows:

- WLAN—Putnam Hardware Co., Houlton, Mo.
- WMAF—Round Hills Radio Corp., Dartmouth, Mass.
- KFCD—Salom Electric Co., Salom, Oregon.
- WEAN—Shepard Co., Providence, R. I.
- WNAC—Shepard Stores, Boston, Mass.
- WLAQ—A. E. Shilling, Kalamazoo, Mich.
- WOAI—Southern Equipment Co., San Antonio, Tex.
- WLAK—Vermont Farm Machine Co., Bellows Falls, Vt.
- WLAT—Charles G. Bosch Co., Burlington, Iowa.
- WLA?—W. V. Jordan, Louisville, Ky.
- WLAR—Mickel Music Co., Marshalltown, Iowa.
- WMAC—F. Edward Page, Fernwood, Cazonovia, N. Y.
- WGAX—Radio Electric Co., Washington Court House, Ohio.

Don't Miss This!

(Radio World, Vol. 1, No. 2, dated October 7, will contain a complete list, alphabetically arranged, of every broadcasting station in this country up to the day of going to press. Be sure to get a copy of Radio World, containing this list, as you will need it during the fall and winter months.)

Radio and the Woman

By
Crystal D. Tector

"MY Dear Crystal," writes a girlhood friend who has just married, "we—that is, John and I—have decided to live in the country. Of course, he had to give in to my whim to have my home where I want it. He dearly loves the big town, I know, and has terrible hankering for his club and all that sort of thing; but I do cherish a little home in the suburbs and all that goes with it. It does seem so cuddly and dear—and he will have to be home every night. But I could not let my selfishness run away with everything, and John finally capitulated provided I would let him install a radio set. He says it will be a nice thing which to entertain the neighbors. Now, what is a radio set?"

Poor misguided thing. I won't betray her by even mentioning her first name; but to imagine that there is even a woman in all this world who does not know what a radio set is! It seems absolutely preposterous. What, my RADIO WORLD readers, do you think I did by way of reply to such a letter—even if it was from an old and very dear friend? Well, I had the impertinence to tell her that if she would buy a copy of this issue of RADIO WORLD, she would find her answer in my department. It just took her off her feet, and she phoned me hoping that I wouldn't write anything to make John angry.

My Dear Mrs. Newlywed—and all others who may be in your state of ignorance—a radio set is just about the one thing that will make your home, especially if it be in the country a perfect haven of joy. Friend Husband and I are commuters—that is, we belong to the vast army of the American citizenry who live a suburban life and come to the city just every so often for our pleasure; but we do notice that whenever we invite any of our big-town friends to visit us, their faces beam with more than customary satisfaction. We were among the first to take up radio. It seemed a heap of trouble and looked like a terrible expense; but we have been more than repaid; in fact, we said, the other night, after listening to one of the most wonderful concerts that I ever heard—the music coming in clear and distinct and absolutely without a blemish—that we would not be without our set for more than a thousand times what it has cost us. And the expense hasn't been so very much at that.

To tell the gospel truth, I would rather have a radio set than a motor-car any day in the week. It affords more keen and honest enjoyment—and it is such an unselfish pleasure! The satisfaction that one gets in entertaining one's friends—and in a manner so absolutely original and fascinating! Why, the other night, we actually heard an entire play—"The Wolf," by Eugene Walter—broadcast from Schenectady. The manner in which it was explained and the clearness in which the lines were spoken and the action brought out, made it a feature of more than ordinary interest. Some of my friends tell me that I am too much of an enthusiast—that I let my happiness run away with me—but I just want to tell you that if the drama can be broadcast so entertainingly as this play, very few trips to New York will F. H. and I make to take in the theatre.

But speaking of the city, I did notice the last time I was on The Avenue—as all good New Yorkers term their famous Fifth Avenue—that several of the better-class tea shops were equipped with radio sets. And I was told that with the new arrangement regarding broadcasting it is very easy to tune in whenever anything particularly interesting is on the ether. In this way, one need not listen to everything that is being broadcast. For instance, there is nothing particularly interesting in a lot of women sitting around tea tables hearing the latest market quotations or the weather reports; but if a good concert or some vocal music or health talks are in the air, why it is an easy matter to tune in and catch them.

And I do feel that the broadcasters would do well to broaden their programs for the women, particularly during the daytime. So much is being done for the farmer—and we all recognize his great and important place in the course of events—but we women should not be overlooked. I would suggest more easy-to-make recipes. Every woman is interested in her kitchen whether she has one or not. I think, too, that practical advice on washing fine lingerie would not be amiss; for few women, to-day, will trust that part of their wardrobe to the laundry. Domestic science is good in small

doses, particularly if it is practical. Rich or poor, we women are all alike so far as our households are concerned. We want to be told how to keep them in order.

And just now, I wish some clever bugologist would radio to me how to get rid of cockroaches!

I have received several letters during the past week from mothers who want to know if they can really count on radio to keep their babies quiet. Now I am not so foolish as to say that you can clamp a pair of headphones on a baby's cranium and let the wave lengths do the rest. Many mothers have that idea. Imagine the poor child if an unruly bit of static should jar it. Then, too, baby isn't going to be very much enthused or its teething be made less painless by listening to the latest market reports or a sermon. Children are uncertain beings and they must cry and be uneasy during a

(C. Central News Service.)

"I did notice that several of the better-class tea shops were equipped with radio sets."

goodly part of their young lives. They wouldn't be normal if they didn't. But I do say that many a mother is going to find in radio a very pleasant form of recreation for her little ones. I know that several of my neighbors do not hesitate to leave their babies with me when they want to go to town for a shopping spree—and that these little ones have been sort of quiet and pleased whenever my radio set has been tuned in—and it generally is.

Friend Husband told me the other day that he read in "Apartments To Let, Furnished," of one that gave "radio" as a modern convenience. That shows what we are coming to. The day is not far distant when every woman who is renting an apartment will examine the radio set as closely as she examines the kitchen.

Mrs. Hattie Kolb, of Chicago, writes me that she is studying the science of radio in the hope of taking a position as radio instructress in one of the Chicago public schools. She says that, in her city, radio will soon be a part of the public-school courses. Teachers will be wanted and she will be a pioneer in the field.

WBAY to Serve a Commercial Purpose with Radio Toll Station

By Golda M. Goldman

Photo by Morris Rosenfeld, New York.

The American Telephone and Telegraph Company's Building, Walker Street, New York City, the home of WBAY. The building is 350 feet high, and the antenna is 100 feet above the roof.

THE commercial uses to which the radiophone is being put are far removed from the knowledge of the amateur. Only he who possesses a set beyond the average is in touch with the manifold ways in which the radio is serving the business world. And now comes the latest development in the commercialization of this power. The American Telephone

and Telegraph Company is presenting New York City with a radio toll-station, known by the call number, WBAY.

While mechanically inclined radioists for years have been contriving receiving sets and snatching messages in code out of the air, it is really only within the year that the perfecting and popularizing of radio broadcasting has

swept the country with a wave of interest. Broadcasting stations appeared almost simultaneously in many of the principal cities, and every dealer whose business was in need of expansion or new blood immediately stocked in radio accessories and did a thriving business. The result, as all fans know, was that Herbert R. Hoover, Secretary of Commerce, found it necessary to call a conference of radio experts who made recommendations of proper wave-lengths to be used for various purposes, so that, today, most stations are working on a 360 wave-length. This necessitates a schedule to which all broadcasting stations in one vicinity must adhere, only one operating at a time, and so avoiding confusion.

When it became evident that the public had become even more interested listening-in than in reading anything except the radio page in the papers, big business men began to consider it as a tremendous possibility for advertising, and the American Telephone and Telegraph Company could have installed over one hundred broadcasting stations in New York's business section alone. The difficulty was that these merchants knew nothing of conflicting wave-lengths, of government regulations, or of the fact that, after installing a station at tremendous cost, they would be able to use it only a few minutes each week. Therefore, as one of the officials put it, "It would have been like taking money from a baby," these stations were never built. Instead, The American Telephone and Telegraph Company decided to extend its own "leased facilities" business, by which private wires for banks, newspapers, etc., are arranged, and so built one of the finest stations now operating, which it plans to rent to advertisers for a quarter or a half hour at a time, much as they might pay for a telephone call.

The public has, however, been educated up to a high standard of broadcast material, and there is no intention of lowering these standards through the manner of presenting the advertised commodity. John Doe, real estate broker, is not expected to announce merely that there will be a sale of particularly fine lots on the following day, with details concerning their desirability. The number of fans who would listen for any length of time to any crudities of the sort would be decidedly limited. Instead it is intended that all matter shall be

(Continued from preceding page.) presented in artistic form, through speeches on allied subjects, the advertising to be subtle and indirect. A life-insurance company, for instance, rather than send out a stereotyped list of benefits to be derived from a policy, will send one of its skilled physicians to give a health talk. It will mean merely this: At present the purpose behind most broadcasting is to entertain the unseen audience to such an extent that it will buy new improvements for its outfit, and stimulate friends to buy, which is of course advertising in itself. So are the present programs advertisements for the artists and lecturers, which in no wise detracts from the value of the donated services. Primarily the present stations emphasize entertainment, with the advertising incidental, while WBAY will only use the entertainment as a means for much valuable advertising.

At present the operation of this plan is held up by the limited number of wave-lengths legally permitted, and the schedule of hours in operation. Relief is expected from two bills now in Congress requesting broader powers for the Department of Commerce, and through the department an increase in the number of wave-lengths available. As most amateur sets will cover quite a wide band of lengths, it would then be possible for more than one station to operate at the same time. With the press of business before Congress, it may be months before this new departure will be inaugurated. Meanwhile, WBAY sends out the afternoon and Thursday evening programs which it started on August 3., and continues to experiment with and perfect its apparatus.

There are many features of this apparatus in the new station which are of note. In the first place, the studio itself has been so skillfully built and arranged that it is echoless. Felt padding on the walls and parts of the ceiling assists in giving to all voices the effect of a clearer enunciation. A second advance in technical apparatus is to be found in the microphone, or transmitter, which like all the rest of the electrical equipment was designed and manufactured by the Western Electric Company. It is so perfected that it is no longer necessary for the speaker or singer to limit his movements to such positions as will bring him close to the transmitter. This gives him the opportunity to exercise all the freedom of action which is so essential a part of a finished entertainment.

A photograph of the interior of the operating room of WBAY, with a complete description of all the important parts of the apparatus, by our technical editor, will be found on the front cover of this issue.

Answers to Readers

Schematic diagram requested by Mr. William Lang, St. Louis.

PLEASE publish a hook-up showing the necessary connections when using a vario-coupler and one stage of amplification of the straight amplifying-type receiving set.—William Lang, St. Louis.

The accompanying diagram shows the proper hook-up for the straight-type amplifying receiver. It will be noticed that the grid condenser and leak are inserted in the grid of the amplifying tube, however, we suggest that it be placed in the grid circuit of the detector tube for better results. Sometimes it is more of an experiment; therefore, we advise the experimenter to try out the grid condenser in the tube of the detector circuit.

Do the radio-frequency amplifiers increase the range of a set. Do loop aeriels work best with such amplifiers?—Albert Murphy, Rosedale, L. I.

Radio-frequency transformers are made to increase the range of a receiving set. They are placed prior to the detector tube and amplify the original frequency-wave before it reaches the detector. Loop aeriels are used almost exclusively in order that most of the unwanted noises may be eliminated. The loop aerial also has the function of giving directional effect upon the signals desired.

Where can I buy plans to build the superregenerative receiving-set invented by Major Edwin H. Armstrong? I have a regenerative set and am getting good results. I would be gratified if I could see a description of the circuit and how it is assembled.—S. A. Masters, Lakeland, Fla.

A full description of the Armstrong superregenerative set was published in RADIO WORLD No. 25, dated September 16, in an article entitled "How to Make a Two-Tube Superregenerator," by Frederick J. Rumford.

I have a short-wave regenerative set which I made, as described in RADIO WORLD, No. 22, dated August 26, with jacks in each stage. The detector works fine, but when I plug in on the second step, signals are not so loud as the detector. What is the trou-

ble? I am using Thordason transformer.—John Kelly, Camden, N. J.

Test each tube out separately. In some cases, amateurs connect up incorrectly the secondary of the audio-frequency transformers. Make a good check-up of this and experiment awhile until you locate the trouble. Test out each and every part as you go along, from tube to tube. See that the proper plate-voltages are had, as well as the correct wiring to the tubes and jacks.

Will you publish a hook-up for a regenerative receiver employing honeycomb coils, 43-plate variable condenser and a variable condenser? Does it matter which binding post you take the lead from in a honeycomb coil?—William J. Kelly, Rockaway Beach, N. Y.

Schematic diagram requested by Mr. William J. Kelly, Rockaway Beach, N. Y.

The accompanying is a diagram of the so-called regenerative receiver. This is the honeycomb type. In the above hook-up, it is very easy to discern where the honeycombs are placed. VC is a variable condenser of 43 plates. P is the primary, S is the secondary and T the tickler. The rest of the circuit is self-explanatory. Either binding post may be connected from the honeycomb to such connections as needed.

What do you consider the best hook-up for a crystal set? My set consists of a two-

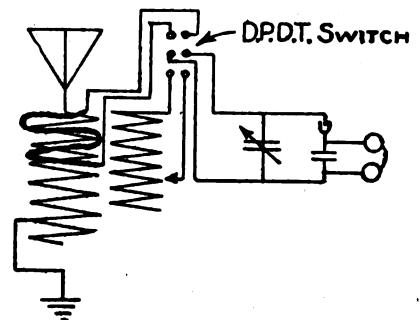

slide tuning coil, one detector, one condenser and a set of 3000-ohm phones. I have seen and tried various hookups, but none seem to work.—Norman Blankenship, Cushing, Okla.

RADIO WORLD No. 11, dated June 10, in "How to Construct One- and Two-Slide Tuners," by George W. May, covers your query fully.

What is the rated voltage for the V-T-1 tubes?—RADIO reader.

As the writer has had years of experience with these tubes, he considers it most essential that you secure a 6-volt battery. In all cases, the tube will draw approximately from 5 to 6 volts. As amperage is the big factor, these tubes are limited to about 1.25 amperes and, in all cases, should not be allowed to go beyond this rating as it may mean the burning out of the tube. It will be found that the tube will work best when kept at a cherry-red glow.

Is there a circuit I could use in which I could have both a tuned circuit and an untuned circuit? If possible I would like to see a hook-up of such a circuit.—James Brandon, Boston.

Schematic diagram requested by Mr. James Brandon, Boston.

There is such a circuit. We have had one drawn, and it is published herewith for your convenience. A double-throw, double-blade switch is used which enables the operator to switch from the untuned circuit to the tuned circuit. It may be said that these principles are used in the Navy type receiver, used both on battleships and in land stations. The idea is to keep the switch placed in—on the untuned circuit—which has a coil about the primary winding. This makes it possible to allow signals of a broad interfering-wave possible. If the operator wishes to eliminate interference in order to read some distant station he will then throw the switch over to the tuned circuit and start tuning in the desired station. This will make a valuable circuit for such work, especially where a close watch is to be kept on everything that is transmitted.

Radio Club Starts School

A RADIO school four nights a week will be conducted this fall by the Hudson City Radio Club, of Jersey City. Code will be the first thing taught because, says the secretary, "a lot of people don't know what they are missing. Don't holler about the ham with his spark and write to the radio inspector when it is some ship on WNY or NAH or some

The Hudson City Radio Club was organized in April, 1920, and incorporated in August, 1921, with thirty-six members. It aims to have at least 136 during the coming year. Anyone interested should write to H. A. Bremer, No. 89-91 Franklin street, Jersey City, N. J.

Civil Service Examination for Junior Radio Engineer

For Men and Women—Opens October 10, 1922

THE United States Civil Service Commission announces an open competitive examination for junior radio engineer on October 4, 1922, at which examination is requested in applications received in time to mail examination papers. Vacancies in the Signal Service at Large, Camp Alfred Vail, N. J.; a vacancy in the position of radio laboratory assistant, Fairfield Air Intermediate Depot, Fairfield, Ohio, and vacancies in positions requiring similar qualifications at Washington, D. C., or elsewhere in the United States, at \$1,200 to \$2,000 a year, or higher or lower salaries, will be filled from this examination unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

As the Commission has had considerable difficulty in securing sufficient eligibles for this position, qualified persons are urged to enter this examination.

Range in salary.—The entrance salary within the range stated will depend upon the qualifications of the appointee as shown in the examination and the duty to which assigned.

Bonus.—Appointees whose services are satisfactory may be allowed the increase granted by Congress of \$20 a month.

Certification.—In filling vacancies in positions with headquarters outside of Washington, D. C., certification will be made of the highest eligibles examined nearest the vicinity of the place at which the appointee will be employed except that upon the request of the department certification will be made of the highest eligibles on the register for the entire country who have expressed willingness to accept appointment where the vacancy exists.

Citizenship and sex.—All citizens of the United States who meet the requirements, both men and women, may enter this examination; appointing officers, however, have the legal right to specify the sex desired in requesting certification of eligibles.

Duties.—The duties of the appointee will be to assist in the development, design and construction of practical and special radio apparatus, and other related work.

Subjects and weights.—Competitors will be rated on the following subjects, which will have the relative weights indicated:

Subjects.	Weights
1. General physics.....	20
2. Mathematics through calculus	25
3. Practical questions on radio engineering	30
4. Education, training, and experience	25

Total 100

Slide rule.—Competitors should provide themselves with a slide rule; in case its use is allowed it will be so stated in the examination sheet.

Preliminary requirement.—The applicant must show that he has been graduated with a degree from a college or university of recognized standing with the completion of at least 118 credit hours, or that he is a senior student in such an institution and furnish proof of actual graduation within three months from the date of the examination. The applicant must show that his undergraduate work included a course in electrical

engineering, and also the usual college course in general physics, general chemistry, and mathematics through calculus. Special credit will be given for experience in a scientific, industrial, or technical laboratory.

Statement of college course.—The applicant must submit a statement of courses taken at college signed by the proper authority of the college or university attended, and give a detailed record of his technical experience and have the vouchers filled out by men professionally qualified to vouch for his ability, fitness, and personality.

Age.—Applicants must not have reached their fifty-fifth birthday on the date of examination. This age limit does not apply to persons entitled to preference because of military and naval service.

Retirement.—Classified employees who reached the retirement age and have served fifteen years are entitled to retirement with an annuity. The retirement age for railway mail clerks is 62 years; for mechanics and post-office clerks and carriers, 65 years, and for others 70 years. A deduction of 2½ per cent. is made from the monthly salary to provide for this annuity, which will be returned to persons leaving the service before retirement with 4 per cent. interest compounded annually.

Photographs.—Applicants must submit to the examiner on the day of the examination their photographs taken within two years, securely pasted in the space provided on the admission cards sent them after their applications are filed. Proofs or group photographs will not be accepted. Photographs will not be returned to applicants.

Residence and domicile.—Applicants may be examined at any place at which this examination is held regardless of their place of residence; but only those who have been actually domiciled in the State or Territory in which they reside for at least one year previous to the examination, and who have the county officer's certificate in the application form executed, may become eligible for permanent appointment to the apportioned service in Washington, D. C.

Applications.—Applicants should at once apply for Form 1312, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C., or to the Secretary of the United States Civil Service Board at any place listed hereon. Applications should be properly executed, excluding the medical certificate, and must be filed with the Commission at Washington in time to arrange for the examination of the applicant.

The exact title of the examination, as given at the head of this announcement, should be stated in the application form.

Preference.—Applicants entitled to preference should attach to the applications their original discharge, or a photostat or certified copy thereof, or their official record of service, which will be returned.

There Is Hope!

Since large corporations find it profitable to provide entertainment by means of radio for their employees in isolated places, this may also be the solution of keeping the hired girl back on the farm.

THOUSANDS of families have only "gone in for wireless" after hearing demonstrations of Magnavox Radio—the Reproducer Supreme.

It is the Magnavox Radio which gives every receiving set its greatest enjoyment and use—doing away with the restrictions and limitations of the individual headset. The receiving set only brings the message, while Magnavox Radio tells it clearly and in full volume to all within reach of its voice.

In perfection of mechanism, quality of manufacture and satisfaction in actual service, Magnavox Radio has absolutely no competition.

R-3 Magnavox Radio with 14-in. horn (here illustrated), is ideal for use in homes, offices, etc. Requires one ampere field current from your filament battery. Price \$45.00

R-2 Magnavox Radio with 18-inch horn for those who wish the utmost in amplifying power; for large audiences, dance halls, etc. Price \$85.00

Model "C" Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Radio.

AC-2-C, 2-Stage - - \$80.00
AC-3-C, 3-Stage - - 110.00

Radio Patents

Invention Will Locate Distant Transmitting Stations

No. 1,427,833. Patented September 5, 1922
Patentee: Frederick S. McCullough, Cleveland, O.

THE invention on which Mr. McCullough has received letters patent, is important to radiotelegraphy—first, because it will determine the direction of distant transmitting stations; secondly, because it will detect incoming electromagnetic waves. In the radio directional-systems hitherto used, there have been employed large antennae arranged in certain shapes and directions, and also loops or coils of wire, these coils generally having a number of turns wound on a square frame with the sides several feet,

Three schematic diagrams showing modifications of Mr. McCullough's system. Figure 6 shows the flat spiral coil enclosed in an evacuated tube.

or several yards, in length. While directional loops of such size may answer for permanent land-stations, it can be readily seen that there are grave objections to them for portable stations such as those on a small boat, and more particularly on aircraft. For the latter, it is essential to have the apparatus in as compact form as possible, and by his system, Mr. McCullough provides means of small size which will satisfactorily determine the direction of transmitting radio stations. Together with his direction finding, he provides for the detection of the incoming electrical oscillations.

* * *

Low-Antenna Signaling

No. 1,424,365. Patented August 1, 1922.
Patentees: Edward H. Loftin, Washington, D. C., and Henry H. Lyon, Hyattsville, Md.

THIS invention relates to radio antenna systems and, more particularly, to stations employing low horizontal antenna or lineal collectors. In a copending application Serial No. 371,557, filed April 5, 1920, the inventors pointed out the necessity for selecting an optimum length for the horizontal component in such

System of antenna for receiving several stations at once.

antenna for tuning to obtain the best results on given wave-lengths. The purpose of the present invention is the devising of a system of antenna for a radio station whereby advantage may be taken with facility and efficiency, of the antenna for general communication with a number of stations employing various wave lengths and having various directions.

Electrical Connection to Prevent Shock

No. 1,422,420. Patented, July 11, 1922.
Patentee: Charles D. Filkins, Schenectady, N. Y.

THE object of Mr. Filkins's invention is to provide a reliable means for providing an electrical connection to a movable element in an electrical device which will allow any desired freedom of movement of

By this device, Mr. Filkins intends to provide a method of making the connections to the movable coil of a variometer which will overcome common disadvantage.

the movable element without interfering with the flow of current.

In the construction of variable-coupling-devices, or variometers, for use in radio circuits it has been customary to provide a

fixed coil and a movable coil which is adapted to rotate with respect to the fixed coil in such a way that the coupling between the two coils may be varied by rotating the movable coil between a position where its plane is parallel with that of the fixed coil and a position where its plane is at right angles to that of the fixed coil. It has been customary in such devices to make electrical connections to the movable coil by means of flexible leads brought from the terminals of the movable coil to fixed terminals located at some convenient place on the apparatus. This method has the disadvantage that it is not possible to rotate the movable coil continuously in one direction, and since the leads are usually located out of sight of the operator there is the danger that the operator will attempt to rotate the coil too far in one direction and break the leads. The leads are, also, apt to be broken by the continual bending which is incident to the normal operation of the device.

By his invention, Mr. Filkins hopes to provide a method of making the connections to the movable coil of a variometer which will overcome the above-mentioned disadvantages; also, to provide a means for holding the movable coil in a desired position and prevent it from moving when the apparatus is subjected to vibrations.

* * *

To Regulate the Flow of Electric Currents

No. 1,426,465. Patented August 5, 1922.
Patentee: Ernest G. Danielson, San Francisco, Cal.

VARIABLE resistance is the subject of Mr. Danielson's invention. Primarily it relates to a composition of matter, useful for providing an electric resistance device, and more particularly to a variable resistance which may be used in a potentiometer.

An object of the invention is to provide a variable resistance device of the poten-

Fig 1

Fig 2

Figure 1 is an elevation of Mr. Danielson's invention mounted on a panel.

Figure 2 is a cross section taken on the line 2-2, Figure 1.

tiometer type in which a metal to metal electrical contact is made between the contact arm and the variable resistance element; to provide a new and useful composition of matter; to provide an inexpensive and reliable resistance element; to provide a simple and inexpensive variable resistance device so constructed

Army Radio Nights

FOLLOWING the success of the first army night broadcasting entertainment from the big station of the Westinghouse Company, at Newark, recently, all Army Corps commanders have been instructed by the War Department to cooperate with local broadcasting stations in entertaining the fans and especially in establishing regular monthly army nights.

Major-General H. C. Hale, of the Second Corps Area, New York, who put on the first army radio entertainment which made such a hit that local fans demanded more, has made arrangements for a monthly program.

The nine corps commanders who cannot stage their own show on army radio sta-

tions, will cooperate with local stations, furnishing band and vocal music, speeches on military science and training, or other forms of entertaining or instructive programs. Very soon now, each of the corps areas throughout the country will have a new source of radio shows.

(Continued from preceding page)

that for the same adjustment of the contacts, the value of the resistance thus chosen cannot be interfered with by such effects as variable contact resistances or loose contacts. Heretofore, variable resistance devices of this nature have comprised a strip of pressed or molded graphite over which a carbon button, carried by the contact arm, is movable. The resistance of the contact between the button and the strip is variable, due to variable conditions of pressure, surface condition of the strip and other causes, so that for any given adjustment of the contact button, different resistances are obtained at different times. In the variable resistance of Mr. Danielson's invention, the contact between the variable resistance and the contact arm is metal to metal, so that the contact resistance remains constant.

RADIO TOOL SET

Consisting of Hammer, Screw Driver, File, Reamer, Awl, Drifter, Tweezers, Gimlet, Chisel. All scientifically tempered tools. Brass Case, nickel plated finish.

Radio Goods that Stand the Test

Manufacturers, send a sample of your goods to our Technical Editor, Fred. Charles Ehlert, 9008 Pleasant Street., Queens, Long Island, N. Y. It will be carefully tested and returned. If your goods satisfy our experts, RADIO WORLD'S endorsement will be published in our merchandise department without charge or obligation of any kind on your part. This is a free service on the part of RADIO WORLD, calling for no expense whatsoever on the part of the manufacturer, except the sending of a sample of his goods.

Super-Sensitive Radiotelephone Head Set

Manufactured by the Teleradio Engineering Corp., 490 Broome Street, New York City.

A RADIOTELEPHONE head set worth testing. It was tested out in various circuits from 200 meters to 20,000 meters. When connected in on short wave-lengths, especially in copying C-W stations and spark stations, in which very good results were obtained, eliminating the hissing noise sometimes experienced in other phones. In copying long-distance transoceanic messages, these phones responded very well. The phones used were of the type C make. They are of solid construction and neat appearance, made adjustable to fit the head. The resistance of these phones was found to be 2,000 ohms.

Na-Ald V-T Tube Socket

Manufactured by Alden-Napier Co., 52 Wil- low Street, Springfield, Mass.

A VACUUM-TUBE socket of genuine condensite. The best part of this De Luxe socket, as it is called, is the patent clip. This clip makes a positive connection to the prongs of the vacuum tube, under all conditions. There is a wiping action across the bottom, and as the tube slips into place this contact is made at the side. The operator using these sockets in his set may be sure that he is free from the open-circuit troubles in this part of his apparatus. As this contact is slotless and made of genuine condensite, it is practically unbreakable. It serves equally well for 5-watt power tubes, as there is ample spacing between the contact strip and the bottom of the base.

Na-Ald Small V-T Tube Socket

Manufactured by Alden-Napier Co., 52 Wil- low Street, Springfield, Mass.

A VACUUM-TUBE socket which requires very little room on a panel when space is limited for mounting sockets. This tube socket is molded of genuine condensite and holds the standard made tube. It is neatly constructed. Spring contacts are provided to make quick connection with the different prongs of the tube. This tube socket is not affected by the heat of the tubes or the heat of the soldering iron when soldering connections.

Na-Ald Condensite Dial

Manufactured by Alden-Napier Co., 52 Wil- low Street, Springfield, Mass.

A DIAL of genuine condensite which will not warp. It allows the dial to run true. It is one of the 3-inch dials on which the fingers may be placed on the knob without covering the numbers on the bevel edge. It is unique in design. With its elimination of excess material, it reduces the absorption losses considerably.

"P-T" Ultra-Sensitive Crystal Detector Contact Wire

Manufactured by "P-T" Crystal Contact Co., Box 164, Boston, Mass.

As all who have worked with crystal detectors are aware, the great disadvantage a solid rectifier presents is the difficulty of

maintaining it in sensitive adjustment. A "P-T" Ultra-Sensitive Contact gave fine results, using a light-contact mineral. When used with an ordinary good specimen of crystal it was extremely stable in operation.

Be sure to keep the crystal free from dust or moisture. Never touch it with the bare fingers, as the natural oil of the skin greatly reduces its sensitivity. If necessary, clean the crystal with soap and water or alcohol, using an old tooth brush.

To secure the best results with the "P-T" contact, use a very short piece of this delicate wire, preferably less than half an inch. Do not coil it, but press firmly on the mineral at right angles, adjusting for best sensitivity and stability; a little practice will enable you to secure both. Use the test buzzer if available as it is of great value. The "P-T" Ultra-Sensitive Contact is ideal for use in pocket, large portable sets, or in any type crystal-set manufactured.

Bakelite Socket for Vacuum Tubes

Manufactured by I. R. Nelson Co., Newark, N. J.

A VACUUM-tube socket made of genuine bakelite. Of neat appearance and solid construction. It is made for the standard vacuum tube. It has for its contacts four metal springs, which make possible instantaneous connection when the four prongs of the vacuum tube are placed into the socket for operation.

Crystal Receiving Set

Manufactured by American Radio Co., Baltimore.

A CRYSTAL receiver of neat design, made to operate over a wave band from 200 to 800 meters. It has for its primary a coil, upon which is a movable band employed to cut in or out the turns of wire needed. This is controlled by a knob on front of panel. The tapped secondary, also, is controlled by a knob and is adjusted so that secondary may be run in or out of primary for the amount of coupling needed. Tested, it was found to record radiophone messages approximately twenty-five miles, using outside antennae. It has, also, two mounted crystals whereby the listener may use either crystal he wishes in case one fails him.

Microstat Vernier Rheostat

Manufactured by Microstat Company, Williamsport, Pa.

THE MICROSTAT is a vernier rheostat on an entirely new principle, of neat design and construction. Its purpose is to allow the possibility of securing exact filament adjustment over the ordinary wire rheostat. Laboratory tests show that it is equal to ten times the possible calibration of a wire rheostat. Where the smallest amount of filament current is needed, especially when working with a critical tube, this rheostat was found to make good its name—"the rheostat with a thousand adjustments." One knob operates the control. No pushing or pulling of knobs. Just turn. The exact calibration of the microstat is due to the gradual entering of two points into a resistance material, which gives the exact and most minute measurements of current to the filament as the operator brings the points together or separates them through the screw handle. The microstat takes up very little room on the panel, with each part carefully and accurately machined.

New Firms and Corporations

Dealers Make Mistake by Rating Receiver Sensitivity in Ohms.

"YES, this is a very good receiver. It has a resistance of four thousand ohms." This is the sort of sales talk that many radio clerks give to unwary purchasers of headsets. In talking so, they not only show ignorance concerning telephone construction and design, but help to create an impression that is entirely wrong. They are responsible for the belief that the sensitivity of a headset is indicated by the resistance of the receivers.

In commenting on this, Frederick Dietrich, president of C. Brandes, Inc., recently said the policy of selling headsets on the strength of their resistance is wrong and should be discouraged by dealers. It not only hoodwinks a misinformed public but is a gross injustice to manufacturers who, for sound technical reasons, do not wish to carry the direct-current resistance of their headsets to such a high value. One might as well measure the horse power of an automobile by the size of its carburetor. The average two-thousand ohm headset is as sensitive and, in many cases, more so than the receiver with a resistance of four thousand ohms. Radio receivers should be rated by their impedance. The Brandes headset is designed to have the same impedance as the average circuit in which they are used, since it has been found that this gives maximum efficiency. This impedance varies, of course, with the frequency of the current. The Brandes company has taken, as a standard, one thousand cycles; and, at this frequency, their headsets have an impedance of twenty-two thousand ohms. It has been found that this is the resistance of the average crystal or tube circuit. This, however, does not guarantee the efficiency of a headset, since there are many other requirements and features that determine the operating efficiency and sensitivity of a radio headset.

Mysterious Selenium

Metal Discovered a Century Ago, Now Important to Radio, Will Do Many Things

*By Maurice Freidlander
Live Wire Radio Co.*

SELENIUM is an unknown substance to the layman. Scientists admit that they have not mastered this mysterious, non-metallic, hexad element which occupies an intermediate place between sulphur and tellurium.

It was discovered by Jona Jakob Berzelius, the Swedish chemist, in 1817. It has taken 105 years to perfect selenium so that, in conjunction with radio, it now becomes a foremost substance for the scientist, inventor, and experimenter. F. V. Madaler, after fifteen years of research, has perfected, at his Selenium Laboratories, the most sensitive cells on a large scale which are guaranteed more sensitive than any cell manufactured.

Selenium is produced in two different forms: rods and powder. There are two different colors: reddish brown and black. When melted it has the consistency of ceiling wax and is shiny black color. In this condition, it is practically a nonconductor; but by passing it through a chemical process, it will change in color and become an electrical conductor very sensitive to the light. That means it will alter its resistance to electricity if more or less light is reflected on it.

This very interesting action of selenium started scientific men throughout the world to discover more about this mysterious metal from a scientific and technical form of view. Selenium, it is claimed, will solve interesting radio problems: seeing by wire and producing electricity from day or sunlight.

Selenium cells are already in use for switching on and off electric lights on a life buoy and in outlying districts; starting and stopping machinery at a distant point, by wireless; measuring the light for exposure of camera films; transferring pictures by wire or wireless; measuring light of sun, moon and stars; registering railroad lights and electric-light meters; reproduction of sound waves as produced by music; avoiding friction in electric clocks, assorting cigars, coffee beans, and, in fact, any article where a difference in shade from white to black is to be distinguished; protection against burglary.

The inventor will realize the big field for selenium. The scientist of the past was unable to make or buy the proper selenium cells and, therefore, could not complete his invention. Selenium cells are not easy to make, as the most important feature must be in permanency in sensitiveness and action.

Selling Goods by Radio

Department of Commerce's "Sell-it-by-Air" Service Hailed by Merchants

TIPPING off American business men, by radio, in regard to foreign sales-openings in order to get the jump on America's competitors for the world's markets is the latest trade promoting stunt of the United States Department of Commerce.

Inquiries for American goods coming into the Bureau of Foreign and Domestic Commerce from consuls, commercial attaches, and other government representatives in foreign countries are now distributed to New England manufacturers and merchants, through the air, by the bureau's Boston office in collaboration with the WGI broadcasting station at Medford, Mass.

The service was tried out one night recently, as an experiment. By first mail the

Parthenology

The dictionary says it is pronounced like this: par-the-nol-o-je and means the scientific study of virginity.

Think of the Seventy Thousand who read RADIO WORLD every week that have never seen your advertisement.

Here is a study in virginity, for RADIO WORLD offers you a virgin field to merchandise your radio goods.

Up-to-date radio "fans," dealers, jobbers read RADIO WORLD—because they get all the radio news—four to six weeks earlier in RADIO WORLD than they can get it in any of the old radio monthlies.

Take this little lesson of parthenology to heart, make a scientific study of this new virgin field RADIO WORLD offers you. Write Fred S. Clark, manager of RADIO WORLD, 1493 Broadway, New York for detailed circulation statement, and tested results on keyed advertisements.

Better still, send us a four-time trial order at \$4.50 per inch, right now, before we double our rates. RADIO WORLD is a marvelous, quick-action result-bringer for classified ads; rate, five cents a word.

next morning, several letters were received from nearby firms. One of the leading New England manufacturers of artificial leather, who happened to be "listening in" that night, learned of two possible openings for his goods—one in Mexico and the other in Colombia. He was much pleased, commending the Department of Commerce for taking advantage of "this most valuable time saving device." In the opinion of another New England merchant, the new "sell-it-by-air" service should appeal particularly to the out-of-town manufacturers and merchants who are not in daily contact with the offices maintained by the Commerce Department in Boston, New York, San Francisco, Chicago, New Orleans and other leading cities.

"For example," says this executive, "there are many manufacturers interested in radio who wish to sell abroad, but who are prevented from keeping in constant touch by frequent visits and telephone calls with the trade openings reported to the government agents. As the radio stations reach many outlying cities, it would seem that this service should be of especial value to more distantly situated business men within a wide radius."

Selling American goods in foreign markets, by radio can be extended readily to

Coming Events

The editors of RADIO WORLD will gladly publish news items of all contemplated radio shows and expositions. Keep us posted by mailing full information.

ANNUAL SHOW OF THE ST. LOUIS RADIO ASSOCIATION, St. Louis, Mo., October 4 to 7, inclusive.

CHICAGO RADIO SHOW, Coliseum, Chicago, Ill., October 4 to 22. U. J. Hermann, managing director, 549 McCormick Building.

RADIO CLUB OF AMERICA. First autumn meeting will be held the last Friday in September. Renville H. McCann, secretary, Columbia University, New York.

CINCINNATI RADIO-AND-ELECTRICAL EXPOSITION, Music Hall, Cincinnati, O., October 2 to 7, inclusive.

TRI-STATE TOBACCO GROWERS' RADIO SHOW, Covington, Ohio, October 21 to 23, inclusive.

NEW YORK ELECTRICAL AND INDUSTRIAL EXPOSITION, Grand Central Palace, New York City, October 7 to 14, inclusive.

NEWARK'S SECOND ANNUAL RADIO SHOW, Robert Treat Hotel, Newark, N. J., October 4, 5, 6 and 7.

SECOND NATIONAL RADIO EXPOSITION, direction International Trade Exposition Co., Chicago, January 13 to 20, inclusive, 1923, George A. King, director of publicity, 417 South Dearborn Street, Chicago, Ill.

PERMANENT RADIO FAIR FOR BUYERS, Hotel Imperial, New York City. Open from September, 1922, to May, 1923.

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, December 21 to 31, inclusive. Direction American Radio Exposition Company, 120 Broadway.

BOSTON RADIO EXPOSITION, AND NEW ENGLAND AMATEUR CONVENTION, Mechanics Building, Boston, October 30 to November 4, inclusive.

SPRINGFIELD RADIO EXPOSITION, Springfield Auditorium, Springfield, Mass., October 3 to 7, inclusive.

SOUTHERN CALIFORNIA RADIO SHOW. Combined exhibition of the Southern California Broadcasting Association, the Southern California Radio Association, and the Southern California Radio Trade Association. Los Angeles, October 9 to 14 inclusive.

PHILADELPHIA RADIO SHOW, October 3 to 7, inclusive.

other parts of the United States, is the opinion of Dr. Julius Klein, director of the Bureau of Foreign and Domestic Commerce. Director Klein pointed out that his Bureau maintains thirty-four district and cooperative offices in this country in addition to the Boston branch. The sending out of the information in each case is a problem for the local manager to arrange with some nearby broadcasting station as all of them have been authorized to undertake the work.

NA-ALD SMALL SPACE V. T. SOCKET

25¢ each, 3 for \$1.00.
Moulded genuine Cantonite.
Requires but small space for mounting. Readily accessible binding posts. No stress metal to interfere with efficiency. Unaffected by heat of bulbs or soldering iron. Probes nickel plated brass binding screws. Flash cut slot. Price possible because of large production.

Special proposition for dealers and jobbers.

IMPORTANT NOTICE:
 While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

How Photographs Are Radioed Across the Atlantic Ocean

IF you were to see some one operating what appears to be an ordinary typewriter, and were to observe that the machine was producing a picture instead of a letter, you would doubtless be astonished, says Henry Smith Williams in "The American," New York. Astonishment would not be lessened when you were assured that the picture thus transcribed by the machine reproduces a photograph that had been taken within the half hour over in Europe. The explanation that the picture had come across the ocean in the form of a radio code would not offer much enlightenment.

Yet that phrase describes, after a fashion, the new method of sending pictures by radio that has been developed by Dr. Arthur Korn, of Berlin. The machine that interprets the code is an ordinary typewriter, merely modified so that it types dots of various sizes instead of letters. The operator who receives the code has nothing to do but strike in the sequence the keys representing the groups of letters that have come by radio.

The picture thus typed out is made up of dots of different sizes, much like the ordinary half-tone printed in a newspaper or magazine. The dark portions of the picture are made up of larger dots; the light portions, of small dots; and the intermediate shades of dots variously graded in size. When this is understood it is easy enough to see how the typewriter builds up the picture, and we begin to get an inkling of what the code is like. The letter A, for example, of the keyboard may be represented by a fine dot, letting white paper show to make a high light; and the letter P, toward the other end of the alphabet, by a coarse dot, building up a deep shadow.

It remains, however, to explain how the

code of grouped letters was made at the transmitting end of the line. And this, it appears, was by far the most difficult part of Dr. Korn's problem.

The method, briefly stated, is to roll a negative of the original picture about a glass cylinder upon which a beam of light plays intermittently as the cylinder revolves. Shadows of varying intensity are thus thrown on the surface of a cell made of the strange metal selenium, which has the curious property of transmitting electricity more readily when illuminated. A highly ingenious mechanism causes a telegraphic key actuated by the current passing through the selenium to produce the dots and dashes of the Continental Morse code in such groups as to represent a different letter for each of seventeen graduations of light, so that the letters from A to P are represented.

The message sent by radio consists only of these groups of letters, and, of course, the typewriter that is to reproduce the picture is constructed with the same correspondence between letters and dots.

The transmitting machine works automatically, sending its groups of letters in sequence determined by lights and shadows of the picture; and at the receiving end an automatic recorder may take the message, reproducing the groups of letters in the same sequence. Then a typist, who knows nothing whatever about radio, may reproduce the picture by merely striking the keys of the typewriter in the sequence called for by the copy.

Thus the mystery of sending a photograph by radio across the ocean disappears—but not the wonder of it. Even when we understand how the thing is done, it still remains a scientific miracle.

Amplifier Using Alternating-Current Supply

THERE has been developed at the Bureau of Standards, Washington, D. C., an amplifier which uses 60-cycle alternating current to supply power for both the filaments and plates. The necessity for storage batteries and dry batteries is thus eliminated. The final form of amplifier uses five tubes and a crystal detector, there being three radio-frequency stages and two audio-frequency stages. A description of this amplifier is contained in a paper by P. D. Lowell, "Note on the development of an electron-tube amplifier which uses 60-cycle alternating current to supply power for the filaments and plates," which appeared in the July, 1922, issue of the Journal of the American Institute of Electrical Engineers, volume 41, pages 488-490. It is expected that this paper will also be available as a publication of the Bureau of Standards in a few months.

Had Your "Ethercise?"
Early Morning Physical Culture Now Comes by Radio Waves

SETTING-UP exercises by radio, beginning at 7 o'clock each morning, is the latest use to which the radio has been put. On September 5, a series of weight-reducing and weight-gaining exercises, designed for various members of the family, was inaugurated and broadcasted from Amrad Station WGI, Medford Hillside, Mass., as a regular feature of its program.

The object of this course is to place at the disposal of all radio users the most approved methods of physical efficiency. Three exercise-classes, lasting fifteen minutes each, are held every morning. These personal efficiency courses are in charge of Arthur E. Baird, head of the Department of Physiotherapy, Caines College of Physical Culture.

While this use for radio is entirely an experiment, being the first time such a course has ever been attempted by radio—in fact, the first time a radio broadcast has been given at this hour of the day—reports indicate that the exercises are being tried by people all over New England. One young woman wrote in that the little girl of the house, arising early one morning, saw her mother bending over and waving her arms with the telephone receiver on her head. The little girl was so frightened that she notified the neighbors.

The three sets of exercises are graded as follows: the first for the normal business man or woman who wishes merely a set of toning-up exercises; the second for those who are overweight and wish to reduce, and the third for those who are underweight and wish to build up. The exercises are accompanied by talks on personal hygiene.

Radiofacts

A VACUUM tube may be used as a rectifier, or detector, of high-frequency oscillations. When connected up to the proper circuit, it performs this function with as much efficiency as the crystal detector.

The chief problem connected with direct transmission by wire and radio, those of amplification with proper modulation, seem to have been solved, and the happy combination of wire phone and radiophone opens up new fields of usefulness to these twin wonders of modern science.

Practically every minute of the day and night the radio news of foreign countries comes over the radio waves. If you have a radio apparatus with vacuum tubes adapted for short-wave receiving, you might as well increase the inductance and capacity, or put up an extra long antenna and listen to the stations in almost any country on the globe.

Arlington broadcasts its time signals 11.55 a. m. to 12 noon, and from 9.55 p. m. to 10 p. m., Eastern Standard time.

Having your aerial higher at one end than the other will not be a disadvantage under the circumstances, but a complete advantage, because it will place it diagonally in relationship to the aerial of your neighbor, rather than in parallel.

Why not a "radio-order house" to supplement the mail-order business during congested shopping periods, such as Christmas?

There is one material in the many places of radio apparatus that cannot be replaced by any substitute scientists have as yet discovered. This material is mica, a mineral substance having unique dielectric properties. It resists the passage of electricity even at remarkably high voltages. It is a material which forms an invaluable function in radio.

Learn the code if you want to get the full enjoyment to be found in radio as a hobby.

In stores where the radio department represents an investment of \$1,000 or more, that department should be put in charge of, not necessarily, a radio expert but a man who is thoroughly familiar with radio parts, installations, and hook-up problems.

It is more than probable that within another year every town of any size in the United States and Canada will have a broadcasting station.

When one considers that a good talking machine costs at least \$100 and a good radio-receiver from \$15 to \$20, it is obvious, as the technical details are perfected, to what extent radio will grip the public.

American radio companies are developing systems of radio communication with Central America, with New Orleans as the main centre for American reception and transmission.

The principal reason why radio-telephony is very little known in Italy is because all the inventors find that if they wish to have a chance to sell their inventions they must go abroad.

The rheostat is necessary because it regenerates the brilliancy of the filament. If the rheostat is turned so as to increase the brilliancy, more electrons will flow in the tube.

Slate, electrically, is a very poor dielectric and nonconductor. It was used in past years as a panel for transmitters, but it has not been used for receivers. At present, nothing is superior to bakelite or hard rubber.

TELERADIO ENGINEERING CORPORATION
 484-490 BROOME STREET NEW YORK

Trying to "Raise" Us
 SOMEHOW the song hits sent out by radio don't seem so charming without the accompaniment of dancing silk-clad legs," says the pert paragrapher of "The Evening Telegraph," New York.

"Just think! When old Doc Snodgrass was examining my heart action with a stethoscope yesterday he all of a sudden calls out, 'Hello! Hello! Is this Central?'"

"The radio thinks it says he that has ears to hear, let him hoist an aerial," was thought out by "The News," Dallas, Texas.

Despite the hopes of inventors and ex-

perimenters the radiophone will never replace the telephone. It's too easy to hand a person "a good talking to" by telephone without giving the other fellow a chance to "talk back." With the radio, one can swear a blue streak into the transmitter and unless the desired recipient is "in tune" he can't hear a word of it.—"The Mail," New York.

Radio has afforded the young thing (the modern flapper) an opportunity to

give her all-too-celebrated "line" a fresh twist, we gather from "The Globe," New York. She adopts semi-technical radio terms under the delusion that it adds smartness to her characteristic lingo. "Quit the static," she warns her "tweddie" when the latter shows signs of becoming boring. Or, not being a mental contortionist, sometimes he fails to follow the trend of her conversation. Then, "Tune in, old dear," she advises him, "there's been a change in the daily program!"

A Broadcasting Corporation to Stabilize Radio

AN interesting plan for putting radio broadcasting on a permanent basis is now being discussed among the makers of radio apparatus, says "Electrical Merchandising."

The plan proposed calls for a "public-service broadcasting corporation" organized not to earn money but to spend it, and to be operated under the direction of—not radio or electrical men—but experienced entertainment people who know the public's tastes in music, lectures, and amusement programs. To the funds of this broadcasting corporation, the manufacturers would be asked to contribute two per cent of their gross sales of radio apparatus. Figuring \$100,000,000 of radio sales this year, it will be seen that the new broadcasting corporation would start operations with an annual budget of \$2,000,000. Independent manufacturers and jobbers and dealers would also be given an opportunity to contribute to the broadcasting pool, inasmuch as all would benefit from a plan which made radio increasingly popular with the public.

In this way, at least, one of the knottiest problems in the whole radio situation seems to be on the way to a solution. With a dependable broadcasting service in operation, the dealer can sell radio outfits with the fullest assurance of his customers' satisfaction.

Navy Day in the Air

RADIO broadcasting will be employed in connection with the celebration of Navy Day designated as Friday, October 27, by Theodore Roosevelt, Jr., assistant secretary of the United States Navy, at the instance of the Navy League. While representatives of the Navy League and other Naval organizations throughout the country will undertake to promote general interest in the Navy and its gallant traditions through meetings, concerts, banquets, and with the aid of the moving-picture industry, a number of the larger and more powerful broadcasting stations have been requested to send out a radio program. In this connection, all Naval stations have been ordered to assist in making Navy Day a national celebration to be remembered by radio fans. Either the Navy or the League will furnish speakers, glee clubs, or other forms of entertainment to radio stations cooperating.

A special program is being planned for the Naval Station, NOF, Anacostia, D. C. It is probable that either Secretary Denby or Assistant Secretary Roosevelt will deliver a speech on the work of the Navy. The Marine Band is scheduled for a special concert which will probably be broadcast from Anacostia.

The gigantic scheme of entertainment for Navy Day will, by the aid of radio, be carried not only to municipalities, but into the very heart of the country in every State, and every fan who owns a radio set should watch for the schedules and prepare to listen in.

WJZ, Newark, N. J., got one step ahead of the Navy League by offering its station one night each month for transmitting speeches and entertainment. Such nights will be known as Navy nights. Naval officials of New York have accepted the offer of WJZ and plan to use, as one attraction, the Naval bands of such ships as may be in port on Navy Night.

Letters from the Navy League to the Department of Commerce District Radio Inspectors have asked their cooperation in securing the aid of broadcasting stations. It is said that most of the large newspaper broadcasters from the Atlantic to the Pacific Coast will also assist in broadcasting Naval achievements.

**Turning Print Into Sound
by Radio**

THE Lee de Forest talking film (or "phonofilm"), can be hitched, after the film is developed, on to broadcasting instruments, it is claimed, so that the voice pictures can be wirelessly great distances and then turned back again into sound waves, says "The Times," New York. So far, the problems of running a typewriter or a linotype by sound waves has not been mastered, but close approaches to it have been made.

By the use of light similar to the photography of sound waves by Mr. de Forest, the printed word has been turned into sound, so that the blind can read by ear. The arrangement of black and white in the ordinary letter causes such varying effects when the letters are intensely lighted and passed over selenium photoelectric cells that the electric current can be controlled by them so as to produce sounds which the blind can interpret into letters.

In both the de Forest invention and the machine which renders the printed word into sound for the blind, the key is the peculiar property of selenium. In darkness this substance is resistant to electricity. In light it conducts electricity. In varying light it modifies the current of electricity passing through it. In the de Forest invention the aperture for the admission of light for the sound-wave photography is said to be in some way controlled by the vibration of the sound. This produces the variations in the sound pictures on the film. When reproduced these variations modify the light which passes through. The modifications of light keep the electrical resistance of the selenium cells in constant variation. The electrical current, is thus controlled by the pictures of the sound waves. The current is magnified by the audion tubes and in turn it controls a diaphragm or microphone, like that of the ordinary telephone receiver, finishing up the process of reconstructing the sound.

**When There's An "R"
There's Radio**

OYSTERS are in season and so is radio. Curiously, the two seasons coincide; if there is an "R" in the month, radio transmission is good. The radio season opened officially on September 1, and is now in full blast. In anticipation of the unprecedented interest in radio during the fall and winter, the Bureau of Navigation, Department of Commerce, is taking steps to minimize interference and insure, so far as possible, strict compliance with the law. The radio inspectors in each of the nine districts have been instructed to cover the principal radio centers and points where serious interference may be expected. On these trips they will inspect stations for license, examine applicants for radio-operators' licenses and determine whether the transmitting stations are adjusted to meet the requirements of the law.

**Claims Spirits Talk by
Radio**

MRS. M. E. CADWALLADER of Chicago, vice-president of the National Spiritualists' Organization, says that she has made plans for the broadcasting of messages from the dead that may be received throughout the length and breadth of the land by all who care to hear. John Slader, a Chicago medium, it is reported, is working with Mrs. Cadwallader. There is no hesitancy in Mrs. Cadwallader's assertion that the dead actually converse with certain members of the living human race and her announcement that these messages can be broadcast, as if they came from the living throat, has been greeted by the true believers with acclaim.

Radio - Frequency Amplification Explained

Interview with Charles Kilgour, Radio Engineer, Brings Out Interesting Information in Regard to Phenomenon of Radiotelephony

ALTHOUGH radio frequency amplification is no mystery to the average amateur, there are many, especially those who have but recently become radio fans, who will be interested in a brief explanation of this phenomenon. Mr. Charles Kilgour, radio engineer, in charge of the corps of engineers employed by the Crosley Manufacturing Company, operators of the radio station WLW, in Cincinnati, Ohio, has made a close study of radio frequency amplification.

"Everyone knows the purpose of the ordinary two-stage amplifier is to make louder the sound as originally received through the detector tube or crystal," says Mr. Kilgour. "This amplifier makes any audible signal louder; therefore, it is called an audio-frequency amplifier.

"The extremely weak electrical alternating currents induced in the antenna circuit of the receiving set have a frequency far too high to produce an audible effect on the head phones. Broadcasting stations usually use the 360-meter wave-length, which means that the current picked up has a frequency of more than 800,000 cycles per second. The lowest note of the piano or organ has about 16 beats, or cycles, per second, while the highest beats approximately 8,000 times per second.

"The high-frequency current picked up from the broadcasting station is called a radio-frequency current, because it is at this high frequency that the message is radi-

ated through space. Combined with the radio-frequency pulsation there is a low frequency variation which is the part we wish to hear. The detector so alters the current that the high-frequency part has no effect on the head phones, while the low-frequency part acts upon them, causing them to give out an audible note. This is called rectification.

"Understanding this, it is apparent that a radio-frequency amplifier does its work before the detector has acted. It is inserted in the set between the tuner and detector. As in the case of the audio-frequency amplifier, a vacuum tube with its proper circuits is used to strengthen the electrical current. In this case, however, this is accomplished before the current has been rectified by the detector. One stage of radio-frequency amplification will not have as great an effect on the output as a single-stage audio-frequency amplifier of proper design, but it has several important advantages.

"If a great volume of output is desired, why do we not use more stages of audio-frequency amplification? We cannot ordinarily use four or six stages because audion amplification becomes very noisy when cascaded in this manner and sounds generated in the tubes themselves have a tendency to drown out the signal. On the other hand, a radio-frequency amplifier does not have this bad quality in anything like the same degree."

Latest Foreign Radio News

THE first radiotelephone system to be established in Japan, will communicate between Fukuoka in Kyushu and Fusan, Morea. It is planned to connect this line with land lines. Considerable delay has been experienced in its installation, but the station, from latest reports, should be in operation. The next installations planned by the Department of Communications of Japan are from Kyushu to Formosa and from Kyushu to Tsushima in the south and from Hokkaido to Saghalien in the north. A company is now being formed to establish a radiotelephone system between Kagoya and Osaka, a distance of about 120 miles.

Effective June 1 last, the legal time in Poland will be the same as that of Central Europe.

French radio-compass stations in Algeria, France, and Morocco give bearings on 450, 600, or 800 meters, as the ship station may desire. For each bearing a charge of 6 francs is made. American ship stations should obtain these bearings on the 800-meter wave.

The new wireless station at Shabolevka, in Moscow, was able to receive messages from the recent Conference at Genoa. Messages are sent by the commissariat for foreign affairs through this station. The receiving department is equipped with three apparatus, all of Russian construction. The station has two masts each 560 feet high.

The wireless coast station at Bonifacio, Corsica, will communicate with any ship desiring information of meteorological order relative to barometrical pressure, wind (direction and velocity), condition of the sky, barometrical tendency, and the visibility and condition of the sea. The land line tele-

graph rate is 3 cents per word and the coast station rate is 8 cents per word. The same information (given by Bonifacio) is obtainable from the station at Marseilles. The rate is the same.

"HAWK JR"

VACUUM TUBE RADIO SET

1. HAWK JUNIOR
DETECTOR TUBE SET

2. HAWK
GYROSCOPIC
VARIOCOUPLER

3. HAWK MIDGET

4. HAWK
JUNIOR

All mail orders
given prompt
attention.
Shipped C. O. D.

5. HAWK SENIOR

6. HAWK AMPLIFIER UNIT

1. Hawk, Jr., Detector Tube Set

One of the most remarkable and thoroughly efficient radio receiving sets of its kind ever produced. It is a non-regenerative vacuum tube set of small compact size equal to many outfits selling at \$50.00, yet retailing at the amazingly low price of **\$10.00**

If you are a dealer you are certain to create a furore in your territory with this set as a business getter.

2. Hawk Gyroscopic Variocoupler

Genuine bakelite and hard rubber. Fahnestock connectors throughout used as standard equipment by the Government. List price..... **\$5.00**

3. Hawk Midget

Most complete efficient detector set at any price. Everything self-contained in unit. List price... **\$5.00**

4. Hawk, Junior

A wonderfully selective crystal receiving outfit receiving up to 40 miles. List price..... **\$10.00**

5. Hawk, Senior

Ideal vacuum tube receiver. Tuner, rotary plate, variable condenser, socket, rheostat, etc., in mahogany finish cabinet, wired and mounted. List price **\$20.00**

6. Hawk Amplifier Unit

Two-step audion frequency amplifier, eliminates tube noises, and distortion is practically nil. List price **\$30.00**

Running Lead-in Correctly from Antenna to House

THE problem of bringing the lead-in wire into the home without interfering with the windows or defacing the house, is a problem. Where an aerial is used in connection with a receiving set, a small porcelain insulator tube, such as is commonly used in electric house-wiring, may be used satisfactorily. A number of special insulators are manufactured for this purpose. Where the lead-in is to enter the building it is essential to bore a hole through the wall, if the building is a frame one, or through the window casing in other buildings. This hole should be just large enough to make the tubing fit snugly. The photograph to the right shows the method of bringing in the lead-in wire through the porcelain tubing. The lead-in wire is often passed through

the tube from the outside and a small loop should be left outside the building to permit the rain and water to drop off both the lead-in and the insulating bushing.

Where it is not considered advisable to drill a hole in the window frame, a small board may be placed underneath or above the window, and a hole drilled through this board. Either of these methods will permit opening the window without interfering with the wire. Both meet the requirements of the Fire Underwriters. Where a window is permanently closed, a small hole may be drilled in the glass and the wire brought through the glass.

The proper grounding of the ground wire sometimes puzzles an amateur. The ground clamp is a strip of metal made to fasten around the pipe. It is held in place by a clamping device. It is important that the pipe be scraped very clean. After being sure that the pipe is cleaned the ground clamp may be attached. The small photograph above shows how to connect the ground to the ground clamp.

Superheterodyne Receiver as Applied to the Armstrong Superregenerative Circuit

By Charles R. Leutz

DURING the past five years, considerable expert engineering has been directed toward finding an efficient and satisfactory method of amplifying radio-frequency energy at short wave-lengths. A glance at the characteristic curves of the present available detector tubes will show a very weak signal cannot be rectified efficiently or completely. In view of this, additional audio-frequency amplification would not be of assistance. All detector, or rectifier, characteristic curves indicate that the resultant audio-frequency current is approximately proportional to the square of the impressed radio-frequency voltage. Therefore, the efficiency of the detector decreases rapidly with decrease of signal until a stage is reached at which the detector almost ceases to

function. Many types of amplifiers have been devised to magnify radio-frequency energy before applying it to the detector; and many have worked very well on long wave-lengths—resistance, inductance, or capacity couplings. However, to use the same method of coupling for extremely high frequencies corresponding to wave-lengths of 50 to 200 meters, most results have been complete failures. There is a good reason for this. The low-capacity reactance existing between the structural elements of the amplifying tubes acts as the equivalent of a dead short circuit around the cou-

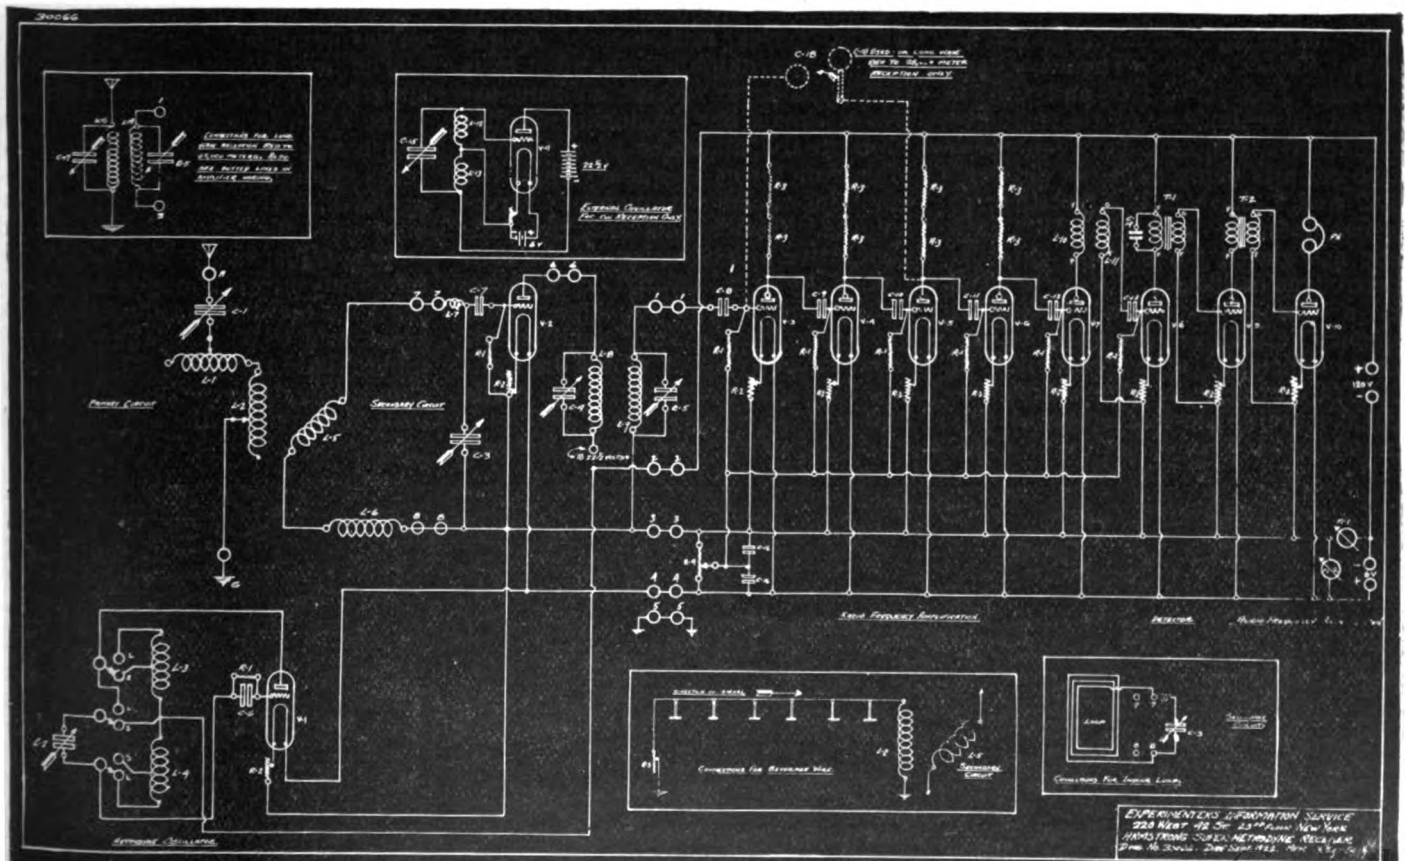

pling medium and prevents a difference—a potential being transferred to the exterior plate-circuit.

This short circuit can be eliminated by tuning with a parallel inductance, but this leads to difficulties in the form of complicated adjustments and local oscillations.

The French and English have constructed special tubes with a view to reducing the internal capacity, by special design. In addition, they have designed special transformers; but the efficient results in each case have been confined to a narrow band of wave lengths; for example, 300 to 700 meters.

Any attempt to increase the effective working wave-length band, particularly toward lower waves, has resulted in failure. It is obvious that if the receiver is to have a com-

Illustration showing the rear view of the panel with the instruments mounted. Seven tubes are used for this particular hook-up. The arrangement should be given close attention, as this is the best method for wiring such a set.

(Continued from page 3)

mercial value a range of wave lengths from, say, 100 to 850 meters must be available with a minimum amount of adjustments and with uniform efficiency over the entire wave-length range.

In December, 1919, Major Edwin H. Armstrong gave publicity to an indirect method of obtaining short-wave amplification, called the superheterodyne. The idea is to reduce the incoming frequency which may be, say, 1,500,000 cycles (200 meters) to some suitable superaudible frequency which can be amplified sufficiently, then passing this current through a radio-frequency amplifier and finally rectifying and carrying on one or two stages of audio-frequency amplification if desired. Transformation of the incoming signal-frequency to the amplifier frequency is usually accomplished by a heterodyne oscillator and rectifier.

This action may be understood readily by referring to the wiring diagram. The primary circuit, C-1, L-1, L-2, is tuned in resonance to the incoming signal-frequency—say, 1,500,000 cycles. The secondary circuit, L-5, L-6, L-7 and C-3, is tuned in resonance to the primary circuit, the coupling between these two circuits being adjusted between L-2 and L-5. V-2 is a rectifier or usual detector tube, and V-2 with the associated parts is an external heterodyne-oscillator. V-3 to V-8 is a resistance-coupled radio-frequency amplifier designed to operate efficiently at a frequency of 100,000 cycles, corresponding to 3,000 meters, the last stage of this amplifier (V-8) also acting as a de-

detector rectifier. The amplifier on the input side is coupled to the first detector by the tuned circuits C-4, L-8 and C-5, L-9, and on the output side to the detectors and audio-frequency amplifier tubes. L-7 is in inductive relation to L-4.

Now, assume that the heterodyne oscillator is tuned to 1,400,000 cycles or 1,600,000 cycles, either position will produce a beat frequency of 100,000 cycles. The combined currents of 1,500,000 cycles and 1,400,000 cycles (or 1,600,000) are then rectified by the detector V-2 to produce in circuit (C-4 L-8) a direct current with a superimposed 100,000-cycle component. This 100,000-cycle component is then amplified by V-3, V-4, V-5, V-6 and rectified by V-8 and the resultant audio-frequency note amplified by the audio amplifying tubes V-9 and V-10. In the case of continuous-wave reception, the best method of obtaining the audible note in the phones is to employ a second heterodyne adjustable to 1,000 cycles either side of the amplifier frequency of 90,000 to 101,000 cycles, and loosely couple this to the amplifier circuit. It is also possible to receive continuous-wave signals but producing oscillations in the amplifier of a slightly higher or lower frequency than the amplifier-tuned transfer wave-lengths. Oscillations and, also, regenerative amplification can be controlled by the special condenser, C-18. This special condenser must obviously have a very small minimum capacity or it would be difficult to stop the amplifier from oscillating.

Reception of spark and telephone

signals can be carried on with equal efficiency and without any distortion, which is odd inasmuch as heterodyning a spark or telephone signal with an ordinary regenerative receiver will result in loss of note or tone. The efficiency of rectification of the incoming signal, when heterodyning depends on the phase relation with the local current. The efficiency of the rectification is a maximum when the two currents are 180 degrees out of phase, or in phase; a minimum when 90 degrees out of phase.

In ordinary heterodyning, the initial phase difference will be different for each wave train from spark transmitters, as the initial phase difference depends on the sparking at the transmitter. The frequency of the two currents are practically the same, and the length of the wave train is small compared with the time required to form a complete beat at audible frequencies. Different wave trains are, therefore, rectified with different degrees of efficiency and the plate current becomes irregular.

The beat frequency is high in the superheterodyne—several beats per wave train being established. The phase angle between the two currents changes through a number of cycles and the initial phase difference need no longer be considered.

The adjustments for 1 C-W and telephony are a combination of the previous mentioned adjustments for spark and C-W reception. Bear in mind that the amplifier circuits should be damped slightly to prevent distortion due to maximum resonance.

Thos. Coke Night, Photographer.

Thos. Oaks Night, Photographer.

Photograph of the front of the panel showing its appearance after the set is finished. This is the Armstrong superheterodyne receiver used for short-wave reception.

The present equipment being used is shown schematically in the wiring diagram, and actually in Figures 1, 2, and 3. The radio-frequency amplifier circuit is designed for 3,000 meters. Special attention has been paid to the effective design of the receiver circuits. L-2 and L-5 consist of a 180-degree coupler and give a 180-degree scale movement to a 90-degree coil relation. The condenser, C-3, has shaped plates to give a straight-line wave-length variation. The maximum capacity of this condenser is very low and the values of inductance are large in order to develop the largest possible potential on the detector grid. In view of the fact that a loud signal is produced with only a fraction of a volt on the detector grid, the ratio of L and C is important. To keep the high-frequency resistance low, the coils are designed to have very low values of distribution capacity and the condensers are of special design, having only one-tenth the resistance of the ordinary condensers. The inductance, L-5, is used in parallel to C-3 to give the first wave-length the range 150 to 450 meters; and L-6 is connected in series to L-5 and both in parallel to C-3 for the second range—310 to 850 meters.

As the mechanical distance between L-8 and L-9 is increased, the tuning becomes sharper and a very high degree of selectivity can be obtained. The output resistors, R-3, can be replaced by iron-core chokes

of proper value. The resistors can also be replaced by inductances and capacities, each tuned to 3,000 meters and give an additional advantage of having the amplifier reject all frequencies but the frequency to which it is tuned. The last stage of radio-frequency amplification is coupled by the tuned transformer, L-10, L-11. A potentiometer is provided for the common grid-leaks on the radio-amplifier tubes providing a means to adjust the characteristic curves to a point when maximum amplification is obtained without chance of the amplifier oscillating. The complete equipment is built in two units each entirely shielded with 10-ounce copper. The phone cords are also shielded with Belden braid. The shields are connected to the negative side of the filament battery.

To use a loop the links are taken out at posts 8 and 7, and loop inserted there using C-3 to tune. For long-wave reception, a large inductance is connected in place of L-9 for the secondary and that coupled to the antenna. The resistance-coupled amplifier will function down to 850 meters. The long-wave reception would not be possible if a tuned radio-frequency amplifier was employed. The first rectifier, V-2, and heterodyne V-1 are not used, of course, for long-wave reception.

Material increases in signal audibility can be made by inserting a variometer in the detector plate

lead, at post 6, 6, tuning the plate for regenerative amplification. In place of tuning the plate, it is also possible to provide inductive coupling between the plate and grid of the detector, V-2, in the usual manner.

The results obtained with this unit have been very satisfactory. The antenna used was 125 feet long and 50 feet high, located in New York City. On 600 meters, spark signals from NGE (Miami), NAU (San Juan), NAR (Key West), NAW (Cuba), NAP (Pensacola), NAO (New Orleans), VCE (Cape Race), and ships in the canal zone were received with sufficient audibility to be heard 50 feet from the telephones. On 360 meters radio-telephone signals from KYW (Chicago), WOC (Davenport), WWJ (Detroit), WHB (Kansas City), WSB (Atlanta), WHA (Wisconsin) were received with the same signal audibility. On 200 meters, a continuous stream of 8th, 9th, 4th and 5th district amateurs were near. All these results were obtained in the late summer with the usual heavy static conditions.

This data, photographs, and schematic drawing of this design were supplied through the courtesy of the Experimenters Information Service, 220 West 42nd Street, New York City. This firm has available for distribution complete sets of blue-prints covering the entire construction of this equipment.

What Makes the Radio Receiver Work, by Donald Van Wyck.

FULLY ILLUSTRATED WITH HOOK-UPS AND SCHEMATIC DIAGRAMS

Radio to Play Important Role in New Aircraft Carrier, "Langley"

By Carl H. Butman

WASHINGTON, D. C.—There is a strange Naval craft cruising about Chesapeake Bay. She looks something like a marine dance-hall, as her upper deck is broad, flat, and unobstructed. She does not carry the usual masts and funnels. No aerials are visible, yet this curious ship answers to the radio call NNC, designated in Naval radio or signal language as "Nan Nan Cast." Being mastless, one wonders about her aerials, but there are both permanent and adjustable aerials and radio masts which can be raised or lowered at will. She is also equipped with new and novel radio apparatus. She carries a number of flyers and many kinds of flying craft.

The vessel is the newly commissioned aircraft carrier, "Langley," built out of the hull of the old collier "Jupiter," the first Naval vessel to be equipped with electric drive. She is now making her "shakedown" or trial cruise in Chesapeake Bay under command of Captain S. A. R. Doyle, U. S. N.

The "Langley," named for the late Samuel P. Langley, the American scientist who was the first practical student of aeronautics and mechanical flight, is a veritable floating landing-field and mother ship for both aeroplanes and seaplanes; but, at the same time, she is a sea-going radio laboratory for the study and development of radio communication between aircraft and ships.

Her great flying deck, which stretches for 520 feet from stem to stern and is 65 feet wide, prevents the erection of permanent masts for radio or other purposes; for her "top sides" must be clear for the launching and landing of her aircraft. Special telescopic masts have been installed amid-

ships, approximately 250 feet apart, fore and aft, which can be elevated when desired, or housed below decks when the planes are being projected into the air by the catapults or alighting from the air on the spacious upper deck. The masts, 50 feet in height and used primarily for the radio aerials, are controlled by hand-operated gears which raise and lower them somewhat as periscopes are operated. When lowered, the aerials are unhooked and stored below or laid alongside the palisades which guard the edges of the flying deck. The masts are elevated simultaneously after the antenna wires are hooked on. This aerial is the principal one used for long-distance communication. Auxiliary antenna are carried aft along both port and starboard sides. These antenna are hung outboard on davits which can be swung in, like ordinary boat-davits, and housed close to the vessel's side when not in use. Primarily these antenna are used to work nearby land stations and aircraft when aloft, as they do not interfere with the operation of the landing deck. At sea, with no aircraft aloft the vessel uses its mast antenna; but when planes are taking off and landing the auxiliary side antenna are used, although the masts could be raised for transmitting a message and then lowered.

Located below decks is the usual radio room found on all men-of-war with its equipment for transmitting and receiving, generators and batteries. The day of a radio house on the "top side" of military ships has passed. To-day the operator on watch sits below instead of "on top of the world" as on merchantmen and liners.

When operating with the radio compass on the Langley, however, the radioman comes up on the top deck and brings his house with him. In this very important work, an original idea has been carried out by the Naval constructors; for ascertaining the position of aircraft, ships or shore stations, the radio-compass house, built on the lines of an elevator, is run up to the top side where it projects above the deck like a pilot house. Its operator, the radioman, can raise and lower it at will, and from its location—aft on the starboard side—he can take bearings without interrupting the operation of planes as they land or depart. The roof of his house, when he is "up," forms part of the deck of the flying platform when he is "down."

Below in the radio room the ship has a regulation Naval 2-kilowatt spark-set for ordinary traffic work; but there is also a 300-watt tube transmitter, consisting of six 50-kilowatt tubes. This set is adaptable for use either as a radiotelephone or as a telegraph apparatus with I C W (interrupted continuous wave) or C W (continuous wave). For communication with the aircraft in the vicinity of the mother ship, either on the sea or in the air, the 300-kilowatt set is used. This is to insure direct and instantaneous communication.

Another feature of this unique vessel is the plane elevators, which raise and lower planes from the storage hold below, and the top of the elevators forming part of the ship's deck when they are "down" like the radio-house roof. Fore and aft are the catapults for launching the planes, as well as the arresting gear for stopping them when they land. Most of the usual "top side" equipment of an ordinary ship is below the flying deck: for example, the pilot house, which is well forward, port and starboard jibcranes for lifting seaplanes from the water, the four 5-inch rifles, and deck houses. Her two funnels project from her sides toward the stern, where they may be turned upward, aft, or downward to keep the smoke from the upper deck.

Great results are expected from the "Langley," the first aircraft carrier of the Navy, and many advanced experiments in radio communication with aircraft are planned. The lessons learned in radio and practical aeronautical operation at sea will be incorporated in the new aircraft carriers which the Navy will build out of two battle-cruisers scrapped by the Armament Conference.

Adding a Tube-Amplifier to a Crystal-Detector Set

MANY amateurs wonder if it is possible to use a one-step amplifier with a crystal set. When one is a crystal receiver and the other a tube amplifier, it would appear to the fan that it is impossible to use them together. However, experienced raidomen have proved that it can be done. According to the accompanying diagram, if the amateur purchases the necessary equipment and hooks up the material according to the circuit he will discover that satisfactory results will be obtained. The amateur must not get overexcited and think that

this is a regenerative set. It is *not!* Nevertheless, with this in view, reliable signals should be secured. One drawback will be the proper upkeep of a good point on the crystal; and if this is obtained with the proper voltages on filament and plate, signals should be heard easily. The operation has already been explained; the various wave lengths are obtained by varying the frequency of the circuits. The alternating current obtained from the distant transmitting station is impressed on the detector of the receiving set.

Constructing a Radio-Frequency Regenerator

By C. White, Associate A. I. E. E.

RADIO-FREQUENCY regeneration is, perhaps, a very misleading and unknown thing to many; but, in reality, it is nothing more than accomplishing a double purpose with a single operation. We are just beginning to grasp the full realization of what may be done by means of regeneration and radio-frequency amplification. The recent invention of Major Armstrong reveals that it is possible to accomplish critical or superregeneration by means of special circuits which, literally speaking, keep the tube from misbehaving. Therefore, we can say that our development in the radio field consists in not only discovering new things but in perfecting our old apparatus so that certain previous troubles are cured. Such is the case of applying radio-frequency and regeneration to the same circuit.

The circuit illustrated in Figure 1 is quite different from the ordinary radio-frequency amplification hook-up. The first very apparent dissimilarity is the use of a tuned plate-circuit that is regenerative; the second is the employment of a crystal detector instead of the ordinary bulb type of detector. The reason for the first change is that we can obtain a slight regenerative effect with a tuned plate type of radio-frequency amplifier; but it must be remembered that good results are obtainable only when the mutual coupling is kept extremely low. If, however, it is attempted to operate the set with a critical coupling between the tickler and the secondary there will develop a serious distortion of the sound waves which will very materially hamper the true reception of music, although the volume will be greater than when the coupling is maintained at a low value. From the electrical standpoint, we are not actually regenerating our signals, but we are so altering the constants of the tuning circuit that the effective resistance, or impedance, of that circuit to the incoming wave will be extremely low, thereby improving reception from a long distance.

The virtue that the crystal detector is practically noiseless in operation explains fully the only basic reason for its use in the construction of this outfit. The one disadvantage of the crystal has been the trouble one experiences in trying to find the sensitive spot, but with one stage of radio frequency it is quite easy to get a good adjustment. However, since we are going to employ one stage of audio-frequency amplification, the total vol-

ume emitted by the detector will be sufficient under all normal conditions. While the bulb detector is by far the more efficient in operation, still the quality of the sound received through a crystal detector is much more natural. A bulb detector can, however, be substituted for the crystal; but the amateur must remember that serious howling may develop, due to extremely critical reaction owing to the fact that the detector tube reacts on the grid of the radio-frequency amplifying tube through the mutual inductance between the secondary and the regen-

though not absolutely necessary, allows a more flexible control and greatly augments sharp tuning. All three coils should be constructed similarly and mounted so that the mutual coupling can be varied. The middle coil, or secondary, should be stationary; and the tickler and the primary should swing in and out from it. If it is so desired, the amateur can purchase coils similar to the ones just described, already mounted, for a reasonable sum, from any radio supply store. The condensers C-1 and C-2 are variable condensers of the 23-plate type, while a grid leak of one megohm and a grid leak condenser of 0.00025 microfarads will suffice. If it is desired to make the outfit capable of extremely critical tuning, I would recommend that either a 43-plate type condenser with a built-in vernier attachment, or a three-plate vernier condenser, shunted around the 23-plate types, be used.

I would like to call the amateur's attention to this fact: If a high value

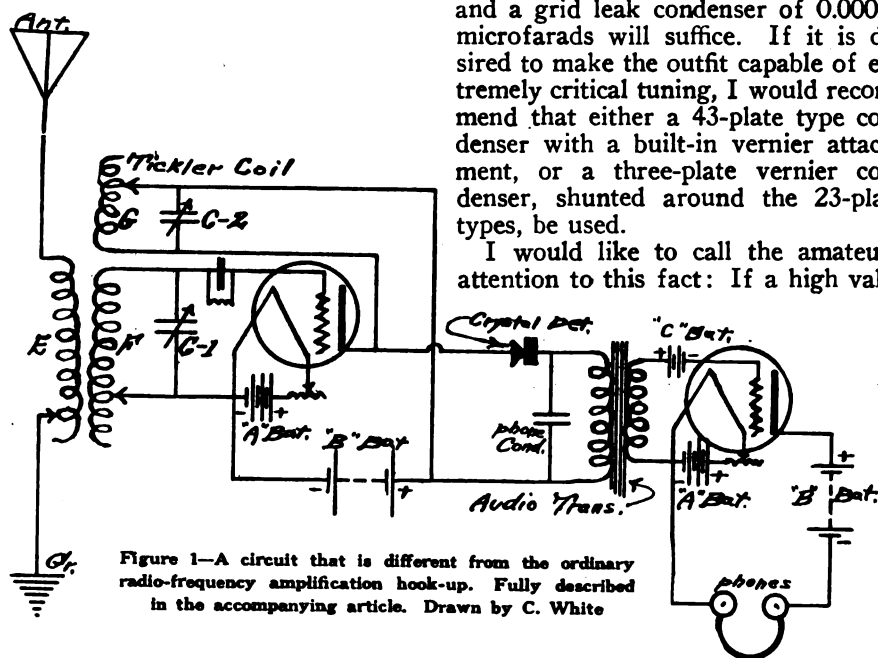

Figure 1—A circuit that is different from the ordinary radio-frequency amplification hook-up. Fully described in the accompanying article. Drawn by C. White

erative tickler element. To avoid all possible trouble of this nature, I would suggest that the amateur stick to the crystal detector in using the particular type of the hook-up explained in this article.

Relative to the actual construction of this outfit, I would advise that the unit E, F, G be made up of three pancake type of inductances mounted in a manner similar to the mounting of three honeycomb coils. Spider-web inductances can be made up easily by cutting out a form about five inches in diameter and dividing it so as to have seven, nine, or eleven spokes. Using a circle, two inches in diameter as a hub of the wheel, the novice should cut out the spokes. Using this form he should wind on about fifty turns. Some may find it more convenient and expedient to put on more turns and tap the same every ten turns; but this added refinement,

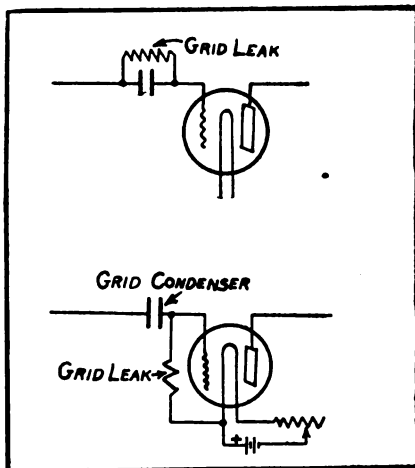

of B-battery voltage be used with the audio-frequency amplifier tube and a small C battery having a variable voltage from two to ten be employed in the grid circuit of the tube as shown in the diagram, he will find that the net resultant amplification will be many times greater than if he had used the customary 45 volts with a U-V 201 type of bulb. Therefore, I heartily recommend that the novice get the maximum use out of his bulbs for amplifying purposes by having a potential of at least ninety volts applied to the plate circuit. In addition to the scientific qualities of this receiver, the price is much lower than any other type of long-distance receiver. This is true because there are no expensive variometers and variocouplers to be purchased. It is possible to make up this outfit for \$15 if the amateur does not wish to use a panel type of mounting.

The Radio Primer

Weekly A B C of Radio for the Beginner, in which Elementary Facts and Principles Are Fully and Tersely Explained

What is the grid leak?

WHEN waves enter the tuner from the aerial, the grid is affected with an alternation of positive and negative waves. The flow of electrons from the filament is helped when the grid is positive, but is hindered, or prevented, when the grid is negative. For our purposes, it can be considered that, when the grid is posi-

Upper diagram—Vacuum tube with grid leak shunted around the grid condenser. Lower diagram—Grid leak shunted around the filament and grid.

tive, the little charges of electricity exchange places with the negative charges flying from the filament in the form of electrons. But when the grid is harboring only negative electricity, it is held a prisoner. There is no place for these charges to go.

The little ups and downs of the radio waves, however, come in thick and fast, and the grid endeavors to take care of them. It has no trouble in getting rid of the positive halves because they flow over to the filament; but the negative halves remain where they are. Soon these negative charges are crowding the grid. As soon as the wave train ceases—and before the next wave train appears—the grid gets rid of these negative charges by making them leak through the most convenient hole. The grid leak is for this purpose. It takes care of the negative charges on the grid. Unless this is done, the action of the tube as a detector would be unsatisfactory if not impossible.

* * *

Can a grid leak be placed anywhere in the circuit, or is there a special place for this to go?

The grid leak has its own place in the circuit and must go there to func-

By Lynn Brooks

tion properly. If placed elsewhere in the circuit, it would not function and would render the whole set inoperative.

* * *

What effect will the grid have on the action of the tube?

Current is normally flowing from the positive pole of the B battery to the plate across the filament and from this point through the telephone receivers. If it were not for the grid, this current would not produce any sound whatsoever in the telephone receivers. But the grid is keeping time changing from positive to negative and keeping pace with the alternations of the incoming signals.

* * *

What happens to this flow when the grid is negative?

We must remember that the electrons are also negative. The electrons coming from the filament are repelled for the instant. When this happens the current flowing through the telephone receivers from the B Battery is interrupted. Since the flow of electrons depends, in turn, on the current. It is easy to see how this current is interrupted by the changing charges on the grid. When the grid is made positive, the electrons are attached and the space current between the plate and the filament becomes a good conductor.

* * *

Does it make any difference if a C battery is used on any type tube used in the circuit of the grid element of the tube?

The C battery has played some important parts; but is not needed in the present type regenerative circuit. It has been used successfully in Major Armstrong's superregenerative circuit.

* * *

What voltage generally is employed on the filament of the vacuum tubes in general use?

The voltage used for lighting the filament of the vacuum used to-day is secured by a storage battery. Sometimes the dry cell is used, but it will be found that this method of lighting filament tubes is an expensive proposition. Stick to the storage battery until something better is invented.

* * *

What instruments are needed for the care of storage batteries?

Storage batteries need great care.

The condition of a storage battery is determined by the specific gravity of the acid solution. An instrument, called the "hydrometer," is used, as shown in this diagram, to test density of specific gravity.

If neglected they will go to ruin. A D-C voltmeter or hydrometer are two instruments that will enable the radioman to keep in touch with the condition of his storage battery. The accompanying illustration shows how the hydrometer is used. These hydrometers may be purchased in most any radio or electrical or automobile shop.

* * *

How does the tube function?

The vacuum tube of to-day has three elements. The grid is connected to what is known as the "input" circuit of the tube. The radio currents pour in through this circuit from the antennae. Since these currents are alternating, the little grid between the plate and the filament will be positive one moment and negative the next. In this respect, it will be kept busy changing its charge thousands of times every second.

* * *

Is it necessary to use storage batteries for filament lighting of vacuum tubes when working with a transmitter employing tubes?

When using vacuum tubes for the transmission of radiotelegraphy and radio telephony, it is not essential to have the filaments heated by battery current as it is when using tubes for receiving, as the use of low commercial-frequencies at the transmitting station does not effect the reception of signals at the receiving station. Filament-heating transformers have been developed for filament heating.

Why the Open Antenna Is Best for the Radio Listener

By C. D. Wagoner

THE radio art suffers, as does all new arts, from "too many ways of doing the same thing," and in no feature does this appear more than in the type of antenna used. The "radio pages" of the newspapers, the semi-technical press, even the higher-grade publications, teem with suggestions as to using the electric-light wires, the telephone leads, barbed-wire fences, wires strung around picture molding and the like, for picking up broadcast signals. It is no wonder that the newcomer in this fascinating field is bewildered to the point of not knowing what to choose from this chaotic array.

Let us consider for a moment the reason for all this. The unfortunate fact appears that, practically, every conductor known may be used to receive signals, because the signal sent out from any transmitter sets up currents in every piece of metal it encounters, such as the metal structure of buildings and bridges, the rails of railroad tracks, and, of course, every electric light, telegraph, and telephone wire that exists above ground or even below ground. Thus it is that our problem is not in finding a conductor to pick up signals for us, but rather in choosing a good one.

Now the fundamental laws governing the best form of receiving antenna were worked out long ago, particularly in popular form by Dr. Austin of the United States Navy. They are simple, indeed. Here they are, expressed in nontechnical language:

1. The higher the receiving antenna, the stronger the signal.
2. The "height" of an antenna is the distance above ground of its "middle point."
3. For any particular wave-length, there is a best over-all length for the antenna.

In addition, a few other simple rules may be added, such as:

4. The antenna should be as far away as possible from other wires, particularly grounded ones.
5. If it is necessary to cross other wires, run as nearly as possible at right angles to these, and as far as you can above them.

With all these rules in mind, and with other considerations which have been proven by practice, let us consider the best form of antenna for the radio novice to install in order to receive broadcast.

First of all, use a *single wire* antenna. This, at least, is just as good as a four-wire antenna, or cage antenna, and in many cases will prove a little better. The *material* of the wire does not matter much. It may be bare or insulated, it makes absolutely no difference which. Copper, phosphor bronze, or brass, may be used; even galvanized iron can be used without

much loss. Of course, it is advisable to use a good strong wire, such as phosphor bronze, so it will not break under strain. It is further recommended that this wire be used whenever possible. Every retail radio store carries this stranded aerial wire, so it is always easy to get.

In regard to the "height" part of the antenna. The *ideal* antenna would be one erected straight up and down, such as a wire suspended from a very tall flagpole. This is because the "middle point" of this wire is higher above ground than would be the case if the wire were inclined, or bent in an L shape. But, unfortunately, few of us have masts 200 feet high, and so some compromise must be sought. The answer is this:

A. Run your wire from your radio room straight up into the air, AS HIGH AS YOU CAN; and then,

B. Run the rest of the antenna approximately horizontally, to a point as high as you can find.

You will then have as good an an-

tenna as you could wish, so far as the question of *height* is concerned.

This antenna is called, for obvious reasons, the "inverted L" type.

If you run the upper part of the L horizontally, then the height of the middle of your wire is the height of the wire above ground. But if the far end of this wire happens to be higher than the near end, you have raised the middle point, and your antenna will receive signals slightly better. On the other hand, if you have to run the antenna "slanting downwards," you have lowered the middle point and the antenna will not receive so well. So try to have both ends of the "horizontal" part of the antenna as high as possible. If you find it possible to make one end higher than the other, by all means do so.

If the far end of the antenna happens to be a tree—as in many cases is the case—remember that during heavy winds the tree will sway greatly. This is likely to break your wire. One way

(Continued on following page.)

Radio Room of "Majestic" the World's Largest Transatlantic Liner

(C. Kadel & Herbert News Photos.)

The steamer "Majestic," of the White Star line, takes particular pride in her radio room. The equipment is of the best, and the room has one of the choice positions on the big boat. The photograph shows the second-in-charge radio operator, L. H. Tamplin, at the C-W panel used for long-distance sending.

(Continued from preceding page)
to overcome this is to attach a pulley to the tree and bring a rope, or wire, from your end insulator over this pulley to a weight, so this weight can rise and fall with the movements of the tree.

Another thing to remember is this: Do not allow the actual antenna-wire to come within seven feet or so of the tree branches. If very near the branches, they might touch during stormy weather, and thus "ground" the antenna; and, also, it is well to keep your antenna some distance away from any other conductor—even a very poor one like a tree. You know that even a *tree* may be used as a receiving antenna, if you don't want to receive very far and if you are contented with a very weak signal.

As to *insulation*. Although the voltage on the receiving antenna is very small, the energy is also very small and every bit of it must be retained. Therefore, you should insulate the receiving antenna well. In dry weather, even a rope is good enough; but let a few drops of rain fall, and the antenna insulated in this manner becomes absolutely useless. Insulators, small ones, probably of porcelain or good composition, should be used. Electric-light knobs, sufficiently large—two inches in diameter at the end—are fairly good, if you cannot get the type developed by the radio concerns who have had long experience in the business.

So put in an insulator at the far end of your antenna, and another where it is supported at the near end, probably by your house. Also, where the wire comes *into* your house, a porcelain tube should be used. Inside the house, where rain ordinarily does not come, insulation is not so important, but it does no harm to run your wires on porcelain knobs even there.

The length of the antenna depends on the wave length one wishes to receive, and it is assumed here that the present broadcast wave of 360 meters is the one in question. Now, there is no special length which *must* be used, but there is a length which is, all things considered, the best overall value. That length is 160 to 180 feet, from the far end of the horizontal portion back to the near end, and down the vertical portion to the receiver itself.

Now, if you use much greater lengths, you will get much louder signals, but you will find it impossible to "tune out" interference from other stations. If, on the other hand, you use much shorter length, you will get even greater freedom from interference than if you use the standard length of 160 feet; but on the other hand you will get a rather weak signal. All things considered, then, 160 feet is the best value for you to use.

A great many people have the idea that if they put up a four-wire antenna, with each wire of the four 40 feet long, they will get the desired effect. Nothing could be farther from the fact. If a four-wire antenna is put up for receiving—a foolish thing to do in any case—*each wire* should be 160 feet long, just the same.

When a wire picks up a radio signal from space, it means that it has "drained the ether" at that point of just so much energy. You can form a mental picture of the waves flowing by, like water waves on a river, and here and there a whirlpool drawing the water down to a reservoir below. So, in the vicinity of a wire which is picking up signals, the ether is "drained dry," and any other wire which is nearby has little energy striking it which it can receive. Thus it is that an antenna inside, or alongside of, a steel building receives very little signal. Therefore, erect your antenna as far away as possible from any other wires, particularly grounded ones. Tin roofs, electric signs, gutters, all are very bad. Several cases have been noted where an antenna was behind a tin-roofed building, and slightly below the level of the roof, and the signals coming from a certain station, striking the tin roof first, were diverted so that the antenna got practically nothing at all. Raising the antenna on two small sticks, so that it was six feet above the level of the roof, brought in roaring signals. A similar experience was found in the case of a huge electric-light sign. Just get the idea that the metal mass casts "a radio shadow," and get your antenna up out of the shade.

There are other forms of electricity other than radio waves, as you will find if you put up an antenna parallel, to and near to your electric-light wires, particularly if alternating current is used. On attempting to listen in on the radio receiver, a deafening, low-pitch, roar will be heard, this being the sixty-cycle current induced in your wire from the neighboring electric-light network. This can be minimized—not entirely removed, unfortunately—by running your wire at right angles to the power wire, and, also, by keeping it as far as possible above it. The same applies to telephone wires, though they will give much less trouble. Ordinarily, you will be bothered in this case only when "Central" rings someone.

We can summarize the situation thusly:

For the best possible receiving antenna for 360 meter broadcast reception, make your antenna according to these simple rules:

- A. Use a single wire only.
- B. Run the wire in the form of an inverted L.
- C. Keep both ends of the horizontal part of the L as high as you can. If one end can be made higher than the other, go ahead and do it.

D. Insulate the antenna well at all points where you support it.

E. Make the total length of your wire, from radio set to far end, not more than 180 feet long or less than 160 feet.

F. Keep the antenna wire as far away as you can from tin roofs, grounded wires, gutters and the like. In any case, be sure to have the antenna **HIGHER** than these.

G. Run the antenna at right angles to any power wires, and as near as you can at right angles to the telephone wires. If you have to choose between the two, pay most attention to the power wires.

If there are any high-tension wires—that is, over 220 volts—near your home, it is absolutely up to you to treat these with the greatest respect. The best advice is not to cross these at all, but if you cannot put up an antenna without doing this, take the greatest care to have plenty of dry rope between you and the antenna wire when you are hauling it up and use heavy wire, well-installed, so as to be sure that your antenna will not break and fall across the power wire.

If you cannot get a length of 160 feet by running up as far as you can (50 feet is about the best average height that the ordinary house or barn will provide) and then running *straight out* with a horizontal stretch, it will be better than nothing to run out horizontally as far as you can, and then make a turn in your line of direction for the remainder of the length. This is true only if you do not turn more than a right angle from the line. If you run across, say, 50 feet to the only tree in the vicinity, and then 60 feet more, at right angles, to some other support, you will have a fair antenna. But do not make the mistake of turning back in the same direction as you started—that does no good at all. See Figure 2.

One of the most persistent errors people make is in believing that the receiving antenna has to run in some definite direction in order to pick up a certain station. Nothing could be further from the truth. Suppose you are some 50 miles from a station—WGY, for instance—and that this station is due north from you. You can run your receiving antenna north, south, east, or west, or any position in between—the signal will come in equally well in any position, as far as the angle itself is concerned. Of course, in one position it might be screened by a gutter, and not screened at all in some other direction; but that is not the point. The point is, that *direction* of the antenna means nothing at all in reception.

The reason that this misunderstanding exists is simply because a little knowledge is just as dangerous in radio as in other things. If the horizontal part of the antenna is *very long*, a hundred times longer than the height, under these conditions the antenna is strongly directional; that is, it receives signals very strongly when

(Continued on following page)

(Continued from preceding page)
they come from one direction and very weak when they come from some other direction. But where the length is, say, 110 feet, and the height 50 feet, a ratio of 2 to 1, the directive effect is absolutely unnoticeable. Run your antenna the direction that gives you the most "open view," unobstructed, toward your favorite broadcasting station, or in the direction of some convenient tall tree that enables you to get the much-desired 160 feet total length, or in the direction that crosses the electric-light line at right angles. All these considerations mean a great deal to you—the consideration of what angle your antenna makes with the line running toward the broadcasting station means nothing at all.

From the foregoing instructions—how to erect the best possible form of receiving antenna—it is hoped that everyone who installs a radio set will strive to forget the swarm of "freak" antennas, ranging from kites, trees and electric light wires, through picture-molding wires, bed springs, and on umbrella ribs, down to wires buried in the earth. Where no other wire is available, it is, at times, necessary to resort to these makeshifts, particularly in military circles; but the novice need not go to these extremes, and should not. They will all work, after a fashion, and if you are an amateur, rather than a radio listener, by all means try them all and be honest with yourself as to the results you observe, but this is written for those who want a radio set for the information it gives them, not what they can do to torture it. So I repeat, forget the freaks and put up a standard type according to the best known engineering principles.

There is, however, another form of antenna which is desirable under some conditions, and which is perfectly correct technically. This is the so-called loop-antenna, which consists of a few turns of wire wound on a frame of some sort. This is really nothing more than a huge receiving coil. In fact, your receiver coils themselves will sometimes pick signals from a powerful station nearby.

The advantage of the loop antenna is that it is very strongly directive. If it is pointed so that its plane points toward the station you want to hear, this station can be picked up, while other stations in a direction at right angles to this cannot be heard at all.

Another advantage of this antenna is that it receives somewhat less atmospheric disturbances than an ordinary open-wire antenna, relative to the strength of signal picked up. This is called the signal-to-static ratio.

However, there is one factor to be carefully borne in mind, and that is, an ordinary loop antenna is much less sensitive than a good open-wire antenna. In round numbers, if you have

Radio Keeps Customers Happy

(C. Kadel & Herbert News Photos.)

In the fashion salon of Welly Soeurs, Paris, France, the radiophone is in daily use for the amusement of both the mannequins who exhibit the styles and the customers. Following the lead set by America, radio is fast becoming popular in Europe. In this particular case, it is said to be the means of bringing many customers to the costumer's shop.

an ordinary antenna, 40 feet in the air, and a 4-foot loop, the latter receives about one one-hundredth as much signal as the former. You have to make up for this by adding *amplification* in your receiving system. This is not a treatise on amplifiers. It is intended to tie down the facts: A loop antenna requires 3 radio-frequency amplifiers added to the receiver system, before the signal is as loud as on an ordinary wire antenna 40 feet high without amplifiers.

The loop antenna, of course, consists of more than one turn, and the more turns the louder the signal it picks up. But there is a limit to the number you can use, and this is a definite limit, not a mere "undesirable limit" as in the case of the open wire antenna and its length of 160 feet. For 360-meter work, a 4-foot loop may have about 10 turns and no more.

There are definite reasons for adopting a loop antenna under certain conditions. In the congested city districts—in apartments, for instance—it is

often out of the question to erect open antennas. Sometimes the landlord flatly forbids it. Here, a loop antenna may save the day. A factor that makes this possible is, that there is a broadcasting station, to-day, in every large city, so that city dwellers have "lots of signal" to work with and can make use of loops without adding many amplifiers.

Again, it may happen that there is an interfering station that bothers you greatly when you try to receive your favorite concert. If it happens that this interfering station is at right angles to the broadcast station you want, a loop antenna will be very useful for you.

It is very probable that some of the sets of the future will be fitted with loop antennas as a part of the system, the receiver and other parts being designed especially for this type of working. When this is done, radio novices will do well to make use of the loop for their work when it will actually do good.

Radiograms

Latest Important News of Radio Garnered from the World Over, and Reduced to Short Wave-Lengths for the Busy Reader.

FIRST radio dramatic critic! "Banco," the new comedy by Clare Kummer and Alfred Savoir, which William Harris, Jr., is presenting at the Ritz Theatre, New York, is the first play to be reviewed by radio. The criticism was sent from WJZ, Newark. The new department is in charge of Miss Brainard, now dramatic critic in addition to her other duties as entertainer for the million or so radio devotees in the Eastern States. WJZ expects this new feature, to be presented weekly, will rival in popularity Bedtime Stories and other standard features.

A series of talks on "Thrift" will be delivered by prominent savings bankers from WJZ. The first speaker is Victor A. Lersner, comptroller of the Williamsburg Savings Bank, Brooklyn, and president of the New York Savings Bank Association, who will tell "How Savings Banks Help Homebuilders."

The new radio station in China calls for the construction of four wireless stations. One in Shanghai is to be larger than any now in existence in this country. Completion of this station will mean direct communication between the United States and China.

Radio inventions are keeping the United States Patent Office busy. Thousand of minds are at work on radio problems. Consequently the patent-office examiners who handle the radio applications have more work than they can conveniently take care of. The office is swamped. Nothing is being done to relieve the condition and the art is suffering as a result. It is about time the force of examiners on this particular job was more than doubled.

The extended fall program of WGY is now effective. There will be four programs a week—on Monday, Tuesday, Thursday and Friday evenings—with an extra program on Friday nights at 10.30, Eastern Standard time. The gentler members of the radio audience will be recognized daily at 2 P. M., when short talks expressly for women will be broadcast.

Lieut.-Colonel A. S. Rowan, U. S. A., who carried the famous "Message to Garcia," twenty-five years ago, when the United States was fighting for Cuban liberty, has been rewarded with a special Congressional medal. Today, perhaps, such a message as that which made Colonel Rowan famous would be sent by radio.

C. W. Horn, formerly in charge of the Westinghouse Radio Service Department, has been appointed to take charge of all radio operations of that company in place of L. R. Krum, who has resigned to become manager of the Erner Hopkins Electric Co. of Columbus, Ohio. Mr. Horn has been interested in radio for the past thirteen years and knows every phase of radio development. His experience on ships has been from the time very few vessels were equipped with radio, until the recent years when every vessel sailing the seas has its radio equipment.

Following a satisfactory radio test Lieutenant Walter Hinton, American aviator flying from New York to Rio Janeiro, has started on another leg of his flight. His seaplane "Sampaio Correia II," is working perfectly, the new engines recently installed functioning in good order.

Many cities of this country are turning toward radio as a convenient medium for license-fee payments. Cleveland has passed an ordinance requiring a 50-cent fee and an examination of the installation by city inspectors. Newark is considering a fee of \$1, and other cities are taking up the idea. Amateur operators look with great disfavor on such schemes, for the Board of Fire Underwriters take care of the electrical safety of the installation, while the Government licenses and regulations control adequately the transmitting apparatus.

Protest has been made in the House of Commons to defeat the plan of Postmaster-General Kellaway against granting to a combine of instrument makers for two years the right of wireless broadcasting in England, and a monopoly of the sale of receiving instruments. The plan, if adopted, will exclude American and other foreign-made wireless apparatus. Captain Wedgewood Benn, Member of Parliament, said broadcasting should be considered as a supplement to newspapers. He declared it marked the biggest development in the dissemination

of information since the invention of the printing press. It was not right, he argued, that the development of radio broadcasting should be left in the hands of a combine.

Broadcasting station WOR is to have a short story contest. Anyone may enter this contest. The stories may be on any subject, the only condition being that they should be read in not less than ten minutes nor more than twenty minutes. The contest will close October 30. The prize-winning story is to be read by its author from the WOR broadcasting station. The title of the story and the name of the author will be printed in the radio program and also announced by radio. The judges are to be selected from men and women of Newark interested in literature. All manuscripts should be addressed to J. E. K., care of L. Bamberger & Co., Newark, N. J. The prize-winning story will be read from WOR on November 14.

Secretary of State Hughes returned aboard the battleship Maryland from Rio de Janeiro, where he attended the opening of the Brazilian Centennial Exposition. He declined to discuss the Turkish war, but said that he had been kept in touch, in a wonderful way, by radio, with the affairs of his office, while at sea.

Lord Hambleton as an "Announcer" at Marconi House, London

(C. International Newsreel Photos)

England's first "radio musicales" have met with great appreciation by thousands who have turned to this form of entertainment. A radio program is broadcast from the Marconi House, London, to hospitals equipped with receiving sets, so that patients may enjoy the music. Lord Hambleton is photographed at the microphone of a radio-transmitter asking all listeners to aid the hospitals. This microphone carries the voice vibrations to the radio telephone-transmitter, where it is then hurled into space

Radio and the Woman

By
Crystal D. Tector

THE average reader may wonder that a woman will take more than passing interest in such an apparently prosaic thing as police broadcasting; but when I read of the wonderful transmitting that had been installed for the police department of our big city of New York, I simply had to be the first of my sex to give it the onceover. Well, there is nothing in all the world just like it; and I really believe that radio will do more to suppress crime than any other element that has been brought to the service of humanity.

* * *

In the first place, it is the one thing that will put the fear of God into the heart of the bandit, the pick-pocket, the hold-up man, and all others of their criminal ilk who have been having a long and hearty laugh at the law's expense. It is going to be impossible, in the near future, as Police Commissioner Enright declares, for any criminal to get beyond radio's clutches. Taking the personal element into consideration, the average criminal may outwit the police; he may slip through their clutches; he may even turn his weapons of destruction on officers of the law and kill them.

* * *

But radio he cannot escape; neither can he wreak its destruction. Its penetrating force is faster than the criminal's fleeting. In no way can he outstrip it. There is no hiding from it. He may—and I doubt if he can—make his way to the ends of the earth; but the wonder waves of the ether will ferret him out. There is no place too small for them to penetrate—no corner too dark for their unrelenting eyes.

* * *

They told us that prohibition would empty the jails and the penitentiaries. I have my doubts. But I do most sincerely believe that radio, within the next decade, will prove to so many hardened criminals that the life they try to lead is so hopeless, they will turn to better things. Watch and see if I am not right.

* * *

I have been asked to give my opinion on the quality of the broadcasting programs of to-day; also, what I think of the proposed payment of royalties on copyrighted music that is being sent over the ether. While I am discussing more serious things, I may say that, in my opinion, we are receiving unusually good programs from all the broadcasting stations, considering the great amount of material that is being sent out. I know how easy it is to criticize and tear down; how difficult to construct. And whenever I hear adverse criticism regarding people or concerns that are trying their best to please, I always put myself in the place of the criticized and ask if I could do any better.

* * *

That the broadcast programs have improved cannot be denied. They are at least one hundred per cent better than those of last spring. The selections are more varied and interesting; and the method of sending them so that the various stations will not conflict is a great step forward.

* * *

The operator of one of the biggest broadcasters in the East told me the other day that every station is trying hard to make still further improvements and to arrange programs that will be still more varied and attractive. Thousands of letters offering all manner of suggestions are being received by every broadcasting station, and these letters are not being taken lightly. Every worth-while suggestion is given the attention it deserves. And I know that an effort is being made to secure better artists.

* * *

There is no doubt that the matter of royalties is—or will be—satisfactorily adjusted. I am told that, in another column of this issue of RADIO WORLD, the matter is presented from its latest news angle. The big broadcasting companies are not going to be niggardly regarding royalties. They want to be fair and generous. The only problem to be solved is how the royalties shall be arranged. That was one of the greatest complexities that beset the moving-picture industry.

* * *

You will gather from all this that I am very much of an optimist so far as radio is concerned. Of that there can be no doubt. I am doubly optimistic. I believe in radio as one of the greatest blessings that ever came to humanity, and from a two-fold point of view; firstly, as a great commercial advantage; secondly, as the greatest form of entertainment that the world has ever known.

* * *

There is absolutely no limit to the entertainment that radio will bring us and there is no possible limit to which that entertainment may be carried. He of the remote hamlet and the sailor on the high seas will some day sit close to the city folk and hear some unborn Caruso sing. And when the next President of the United

How a Singer Sends Her Voice Over the Ether

Miss Estelle Taylor, soprano of "Thorns and Blossoms," is photographed singing for radio. Her voice is directed at the horn which connects with a microphone transmitter. In turn, the microphone delivers her voice to the radio transmitter which throws it on the air. The mechanism of the microphone is similar to that of the telephone transmitter. The horn assists in picking up the music of the piano, and blends it with the singer's voice. It is all very simple, but the great wonder of it is how this music is carried many thousands of miles without a flaw.

States is elected, that news will reach the remotest perlieus of the South Sea Islands almost as soon as it is known in Chicago.

* * *

Miss Mary Hope, Atlanta, Georgia, writes to ask if I will help her to solve several hook-ups for a prize contest. Well, Miss Mary, that hardly would be fair. Why not go to it on your very own. You will be better satisfied in the long run. But, send me the hook-ups and let me see what I can do with them.

* * *

Mrs. H. J. S., Elmira, New York: If you are in doubt regarding your set, write our technical editor. He will give you the most expert advice and will publish a diagram, if that is necessary, to show you how to set things right.

* * *

Carrie P. Y., Pendleton, Oregon: It is impossible to say how many women are employed in the factories turning out radio apparatus in this country. I do not believe that this has been made public as yet—I have been too busy with other radio matters to find out. However, there must be a great many. I understand that women are particularly adapted to certain branches of radio manufacturing.

* * *

Miss Carrie F., Montgomery, Alabama writes me that she caught station WAFYZ, and wants to know what it is. No such place, my dear. Some mistake somewhere. There are no stations with five call letters.

* * *

A St. Louis girl writes that a friend has presented her with one of those miniature sets you read about. Hers is in a case made to resemble a prayer book. I wrote her that her young man is one of those bashful things who hasn't the courage to ask her if she goes to church. Thinks he'll find out anyhow.

The Week's Important Radio Even

Realizing the entertaining value of the radiophone, officers of the Hebrew Orphan Asylum, New York, installed an outfit for the benefit of the eleven hundred orphans there. With this regenerative set and two stages of amplification, results are highly satisfactory.

MICROSTAT VERNIER RHEOSTAT

The most sensitive filament control and quickest, easiest tuned. This microstat has ten times the possibility of exact filament adjustment as over the ordinary wire rheostat.

It eliminates grating and interfering noises, has single knob adjustment and is far more durable being made of better material with greater care.

This microstat takes up less room on the radio board, is neat and compact. The exact calibrations of the microstat are due to the gradual entering of two points into the resistance material of our own composition which gives us exacting and most minute measurement of current to the filament as the operator brings the two points together or separates them through the screw handle.

Broadcasters Will Pay Royalties for Copyrighted Music

MORE than one million dollars per year additional revenue is expected to enrich the coffers of the American Society of Composers, Authors and Publishers, says "The Clipper," New York, when final arrangements are completed between the society and various radio broadcasting-stations that perform copyrighted music for profit, take out performing rights licenses and pay an equitable fee for such rights.

The most definite step taken by the society to license the radio stations was on Wednesday, September 20, when a conference was held at the A. S. C. & P.'s rooms, between various radio representatives and organizations interested in copyright and the rights of such copyright owners. All of the representatives of the leading radio interests acknowledged the rights of copyright owners to collect a fee when their works were performed for profit, and the suggestion by E. C. Mills, chairman of the executive board of the Music Publishers' Protective Association, who presided at the conference, that \$5 per day be a minimum fee for each station, graduating up to a larger fee, was favorably received by those representing the important radio corporations. At this rate, the tremendous amount that will be paid the society by the radio stations will easily reach the million-dollar mark.

Many interesting questions were brought up at the conference, the stenographic report of which covers more than 100 pages and copies of which will be available to those interested as soon as they can be printed and bound. Most of the questions that arose were made by the radio men for points of information, and practically all of them were answered by E. C. Mills, who was later warmly congratulated.

Those present at the conference were: American Society of Composers, Authors and Publishers—Nathan Burkan, general counsel, and J. C. Rosenthal, general manager. Author's League of America—Mr. Williams, president, and Eric Schuler, vice-president. Music Industries Chamber of Commerce—Alfred L. Smith, general manager. Music Publishers' Association of the United States—George Fischer, president, and Alfred L. Smith, secretary. Department of Commerce, United States of America—Arthur Batcheller, Radio Inspector of Second District. American Telephone and Telegraph Co.—A. H. Griswold, S. L. Ross and C. H. Fuller. Radio Corporation of America—J. C. White, and Ira J. Adams, counsel. General Electric Company—H. E. Dunham, counsel, and M. P. Rice, in charge of WSY station. Westinghouse Electric & Manufacturing Company—William E. Easton, vice-president; Calvert Townley, assistant to the president, and C. B. Popenoe, of WJZ broadcasting station. G. Shirmer, Inc.—O. G. Sonneck, National Radio Chamber of Commerce—Mr. Lewis, secretary. Music Publishers' Protective Association—E. C. Mills, chairman of the executive board, presiding at the conference.

Radioisms

A RADIO Beginner is a man who spends \$90 on parts to build a \$19 set.

A Radio Fan is a man who believes that God made the air for broadcasting.

An Amateur is a man who is convinced that the devil invented broadcasting merely to fill the atmosphere with noise to smother the sweet sounds of the dah-de-dah.

The Dah-de-dah is a peculiar bird who is never satisfied with QRK, but is ever looking with longing eyes on DX. He abhors ORN, but manages to stand it, yet QRM, particularly from broadcasting stations, brings tears of anger to his eyes.—"The Globe," New York.

California Leads in Broadcasting Stations

Service Continues in All but One State

By Washington R. Service

BBROADCASTING still continues in all but one State in the United States, notwithstanding pessimistic reports from some quarters that this service, which is likened to a fad, is falling off and likely to collapse. On September 21, there were 510 active broadcasting stations, according to a survey by the Radio Section of its limited commercial stations, operating on 360 meters.

The list of broadcasting stations published on pages 12 and 13 of this issue of RADIO WORLD is a complete record of licensed stations in the United States and Canada, alphabetically arranged. It has been brought up to date—every station officially reported from Washington received up to the time of going to press is included. All new stations are published in RADIO WORLD from week to week, as soon as received from Washington.

California still leads with 66 stations sending entertainment, news, and information; Ohio is second with 34; and New York third, having 28 stations. Wyoming brings up the rear, without a single station. Every other State of the Union has one or more transmitting stations carrying entertainment in some form.

Class B Applications

Several applications from larger broadcasting stations for the class-B license, permitting the use of the 400-meter wave, have been received by the Department of Commerce, but to date only two have been authorized to transmit on this wave. They are the "St. Louis Post Dispatch" and the Westinghouse Station, Chicago. The officials in charge of the licensing of radio stations do not anticipate that more than a dozen applications for the class-B license will be received, as only the most powerful stations carrying high-class entertainment regularly may hope to qualify.

Four New Licenses

During the past week, four licenses were issued for regular 360 meter broadcasting stations, as follows:

WLAX—Greencastle Community Broadcasting Station (Putnam Electric Company), Greencastle, Indiana.

WLAS—Hutchinson Grain Radio Co., Hutchinson, Kansas.

WPAN—Levy Bros., Dry Goods Co., Houston, Texas.

WMAG—The Tucker Electric Co., Liberal, Kansas.

The list by States is as follows:

Number of Broadcasting Stations by States on September 21, 1922

MAGNAVOX
brings City Entertainment
and Education
to the
Farm

*How Science has bridged
with wireless the miles
between city and country*

NOW to the health and independence of farm life, you can add the large city's most envied advantage—access to wholesome, inspiring entertainment.

Within the past few months more than half a million radio receiving sets have been installed by amateurs, mostly to hear the daily programs of Concert and Dance Music, Vaudeville, Speeches, Sermons, etc., broadcasted from central stations in all parts of the country.

Without a Magnavox Radio no wireless receiving set is complete. It makes it possible to hear all that is in the air as if it were being played by your phonograph.

Any radio dealer will demonstrate for you, or write to us for descriptive booklet and name of nearest dealer.

The Magnavox Co.
Oakland, California

Radio Patents

John Hays Hammond, Jr's., New System for Transmitting Radio Waves

No. 1,425,523. Patented August 15, 1922.
 Patentes, John Hays Hammond, Jr.,
 Gloucester, Massachusetts.

JOHAN HAYS HAMMOND, JR., one of the most prolific inventors in the radio field, has added another patent to his long list. It is an improved system for transmitting electradiant energy; particularly where a control station, and one or more auxiliary control stations, is operated. In this new system means is provided for informing the operator at any one of the auxiliary stations as to the responsiveness of the central station.

A particular embodiment of this invention comprises an antenna or open aerial circuit, which includes an inductance and which is grounded through the

Diagrammatic representation of a transmission system constructed in accordance with Mr. Hammond's invention.

inductance. The inductance forms the secondary of a transformer which includes a primary inductance which is in a circuit controlled by a normally open switch and arranged to be energized by a high-frequency electric alternator. A variable condenser is connected in a well-known manner to form with the primary inductance, a closed oscillatory circuit, which is preferably tuned to the natural frequency of oscillation of the open aerial circuit.

The normally open switch is arranged to be controlled by an electromagnet, one end of the winding of which is connected by a conductor to a fixed terminal. The other end of the winding of the magnet is connected by a conductor to one pole of a battery the other pole of which is connected by conductor to a switch which is arranged to swing into and out of engagement with the fixed terminal, and which is normally held open by a spring.

For controlling the normally open switch either from a central station or from anyone of a plurality of auxiliary stations, an electromagnet is suitably arranged.

For Testing Transmitters or Receivers

No. 1,426,897. Patented, August 22, 1922. Patentes: Harold D. Arnold and John P. Minton, East Orange, New Jersey.

THIS invention relates to a method of and system for testing the comparative efficiency of telephone transmitters or receivers, and for testing the component parts thereof, such as their diaphragms and also the granular carbon employed in the transmitter.

The invention makes use of a source

of sound; for example, a telephone receiver, which acoustically operates the apparatus under test, that is, the transmitter, or receiver, or component parts thereof. A source of energy is connected to the receiver and the alternating-current energy produced thereby in the apparatus under test is measured and compared with the results obtained when other apparatus is tested under like conditions. In this way it may be determined if the element tested—transmitter, receiver, diaphragm, or granular carbon, measures up to the chosen standard of efficiency.

It is well known that telephone currents produced by speaking into a transmitter are very complex and may be considered as made up of currents of various frequencies, extending over the acoustic range. It is desirable in testing telephone devices to duplicate actual

Figure 1 shows a perspective view with parts broken away, of the variable inductance; figure 2 shows, diagrammatically, a testing system that may be used; figure 3 indicates diagrammatically a wave filter; and figure 4 is a plan view of a coil supporting plate forming a part of the inductance shown in figure 1.

working conditions as nearly as possible, while obviating the necessity of actually employing currents produced by the voice. To this end the invention provides a special form of generator for energizing the receiver which actuates the element under test. This generator supplies current which continuously and cyclically varies in frequency over the important part of the voice frequency range, thereby testing the apparatus at all those frequencies which are most important in speech.

* * *

To Aid Direction Finding

No. 1,425,137. Patented, August 27, 1922. Patentes: George Maurice Wright, Lyngrove, Chesterfield, England.

IN the "aperiodic aerial" system of direction finding, using two fixed aeri- als and a radiogoniometer, it is necessary to

make the coupling between the tuned search-coil circuit and the aerial circuits as tight as possible. This condition is desirable firstly in order to minimize the loss in signal strength due to the method of tuning; and, secondly, to increase the ratio of signal strength to stray effects which tend to distort the ideal polar diagram of the system.

A radiogoniometer usually consists of windings disposed on two co-axial cylinders, the inner cylinder carrying the search coil winding and being capable of rotation. In order to make the coupling between field and search-coil windings as large as possible, it is necessary to make the cylinder carrying the search coil of as large a diameter as possible in order to bring the windings close together. The magnetic field inside the outer winding is, however, not uniform but is more intense in the neighborhood of the conductors themselves. Consequently, as the search coil is rotated, the

A radiogoniometer comprising two stationary coils in planes at substantially right angles, and a rotatable search-coil comprising two windings in planes at an acute angle with each other.

law of coupling between it and each field winding does not follow the sine law required theoretically and errors are produced.

In the positions of symmetry, i. e. when the plane of the search coil either coincides with that of either aerial coil or lies midway between the two, no error will exist. Consequently the error curve takes the form of a cyclic variation making four complete cycles per revolution of the search coil and if one aerial coil is parallel to the 0-180 degree line of the scale pointer system, then the points of zero error will be 0, 45, 90, 135, etc., and the points of maximum error about 22½, 67½, etc.

According to my invention I construct a radiogoniometer having a double search coil with its two windings in planes making an angle of substantially 45 degrees.

The coils may be connected in series. In this case the total E. M. F. induced in the winding by the currents in the two aeri- als is given by the algebraic sum of the E. M. F.'s in the individual coils. And though the difference of each E. M. F. from the ideal case may be quite considerable, yet since the differences are of opposite sign they cancel out and the radiogoniometer will read correctly in all positions of the search coil.

Eight Radio Stations for Alaska

Also, Five New Radio Beacons for Lighthouses Attest Government's Liberality

EIGHT new radio stations have been opened in Alaska and five new radio beacon-stations have been added to lighthouses.

The opening of the Alaska stations means the introduction of radio broadcasting in Uncle Sam's northern territory on a large scale. The geography and limited population of the territory make the general use of radio receiving sets somewhat difficult of achievement, but government officials suggest that the stations may be used in connection with community radio-sets installed in town halls or mining camp central buildings for the enjoyment of inhabitants in these various localities. The stations have been opened at Alitak, Akutan, Libbyville, Funter, Naknek, Chisik Island, Snag Point and Koggiung.

The installation of radio beacon stations in lighthouses is another step forward in installing radiophones in isolated spots. The new installations are primarily for code signals, but can be adapted to radiophone receiving-sets. The new installations are being made at Boston, Nantucket, Cape Charles, Columbia River, and Puget Sound.

If financial appropriations permit similar equipment will be installed at Delaware Bay Lighthouse, Los Angeles, and Blunts Reef. These are in addition to the two new radio beacons at Diamond Shoal, Cape Hatteras, and the San Francisco Light Vessel. Three radio beacons have been in operation in New York harbor for over a year: Ambrose, Fire Island and Sea Girt.

Army Air Service Broadcasts

TWO stations of the United States Army Air Service have made decided hits with the radio fans by broadcasting on a small scale—"entering the newest field of indoor sports," they term this public service.

The 91st Observation Squadron, stationed at Eugene, Oregon, on Forest Fire Patrol duty, is using the radio station at its flying field during spare time to entertain neighbors within a good radius and has met with marked success. There is no other station of any size in that locality broadcasting, so they are putting on a program chiefly of phonograph music and short talks on forest fire fighting and prevention, with occasional entertainment of other kinds. It is their intention to build a regular broadcasting room in order that they can carry music by a local orchestra. Great enthusiasm is said to be shown by local fans who listen in at home or attend the loud-speaker concerts held in the city park on special nights.

Brooks Field, at San Antonio, Texas, also has an "amateur" broadcasting station where the officers and men of the aerial squadrons put on a varied musical program. his created considerable interest in the surrounding territory, according to letters received by Lieutenant McGregor, of the Field Communication Department. The post jazz band, augmented by piano, saxophone and cornet solos, furnishes the latest music nightly. The slogan, "Own your own radiophone," has come to be very common thereabouts.

"RADIO" VARIABLE CONDENSERS

Is America on Threshold of New Inflation?

THE expansion of business in the United States since the first of the year has been so rapid as to raise the question as to whether it was going too fast for the future good of the country—particularly as to whether the rest of the world was ready for so much prosperity in America, writes John Oakwood, in "Forbes Magazine."

Since the first of the year there has been a marked increase of commercial and industrial activity in the United States, reflected in rising prices and expansion in credit and Federal Reserve currency. This development of activity has been retarded by the coal and rail strikes.

Accompanying the expansion in domestic business there has been an expansion in the evident ability of the world to buy and sell from and to the United States, coupled with the ability to command a large volume of credit here; as to Europe in particular, there has also been a strengthening of her position to do business with the United States, and also to command a considerable volume of credit here.

As to the future, there is good evidence that world conditions justify the expectation of a rising volume of sound business activity and prosperity for the United States, but halting business in several of the nations of Europe and unsatisfactory credit conditions in them serve warning against any expectation of a boom.

Therefore, business expansion in the United States, since the first of the year has perhaps been a bit too fast for the world, and the industrial and commercial slowing up caused by the strikes may not all be lost time.

Radio Goods that Stand the Test

Manufacturers, send a sample of your goods to our Technical Editor, Fred. Charles Ehlert, 9908 Pleasant Street, Queens, Long Island, N. Y. It will be carefully tested and returned. If your goods satisfy our experts, RADIO WORLD'S endorsement will be published in our merchandise department without charge or obligation of any kind on your part. This is a free service on the part of RADIO WORLD, calling for no expense whatsoever on the part of the manufacturer, except the sending of a sample of his goods.

Vacuum-Tube Socket

Manufactured by Teleradio Eng. Corp.,
484 Broome Street, New York, N. Y.

A VACUUM-TUBE socket of standard make. It takes very little room on the back of the panel board. The holder, which is made of polished aluminum, holds the standard tube manufactured by various concerns. The base, which is of a composition insulating material, holds four contact posts. Spring contacts are used to make direct connection with the prongs of the tube.

* * *

Aerial Plug

Manufactured by G. M. Jost, 1 Union
Square, New York, N. Y.

THIS is a plug of simple and rugged construction. It consists of a housing of insulating material, having a blinding post on either side, with a condenser. The condensers employed are particularly of good construction. The whole unit is so assembled as to make a rigid, compact, and efficient con-

How Old Is News?

A month or two after it happens—is that news? Think of putting away your Sunday newspaper and letting it age from four to six weeks before reading it.

Radio is the most rapidly moving industry to-day. More new ideas, inventions—new patents—are coming to the front each week in radio than in any other field.

Yet some people are still reading a monthly radio paper when they could read (and at less cost) RADIO WORLD, the national illustrated weekly, and get their radio news the week it happens instead of from four to six weeks afterwards.

Some business men are still paying four times the cost of an advertisement in RADIO WORLD, the weekly, and inserting their advertising in monthly radio-publications, jammed between a hundred or more pages of similar radio "ads."

RADIO WORLD, published four or five times each month, is not as bulky as a monthly. Each advertisement is next to interesting text matter, so that it is seen, remembered, and brings results.

Gentlemen, to-day it's the WEEKLY that pays advertisers best. RADIO WORLD is the Saturday Evening Post of radio.

It's the best advertising buy in the radio field with its seventy thousand fan-readers, besides having more dealer-readers than any radio-dealer publication.

Put RADIO WORLD on your advertising schedule. There is no duplicate circulation in this weekly—as it's the only national illustrated radio WEEKLY.

denser. The average capacities were approximately .0003 mfd. When testing for receiving, the plug gave very good results whether the current was turned on or off. At a distance of 40 miles from a broadcasting station using a two-stage amplifier regenerative set, receiver gave satisfactory results. The plug was not so efficient when the crystal receiver was used. A screw plug is provided so that the unit may be connected to any lighting socket in the home.

Radio Exports for July Total \$385,861

RADIO-EQUIPMENT exports from the United States, during July, were valued at \$385,861 and totaled 225,475 pounds in bulk. Most of the apparatus went to England, where \$139,027 worth was forwarded. Cuba was second, importing \$42,415 worth.

INTERNATIONAL RADIO SHOW, Madison Square Garden, New York City, November 20 to 25, inclusive. E. C. Buchignani, director of publicity.

Shall Foreign-Made Vacuum Tubes Be Admitted Free of Duty?

THE report from Washington that Senator Joseph S. Frelinghuysen, of New Jersey, has introduced an amendment to the McCumber-Fordney tariff bill, now before Congress, placing foreign-made vacuum tubes on the free list, created quite a stir in radio-manufacturing circles in this country. Senator Frelinghuysen was prompted, probably, by the report that reports made to him indicate that there appears to be an underproduction of this important radio article in this country—a stand in which he is upheld by many dealers, as several of the appended letters will attest. If there is to be an effort to corner tubes in America, there will be many who will not oppose Senator Frelinghuysen's measure, particularly as Great Britain announces that she has granted patents on a new tube which will equal anything manufactured elsewhere in the world.

On the other hand, the proposed Frelinghuysen amendment is opposed by many American manufacturers and dealers who believe that the American article is so superior to any made in Europe, especially those manufactured in Germany and which, it is expected, will be exported to this country in large quantities, that, should any underselling of the American product be permitted, radio, in general, would suffer.

American tube manufacturers are endeavoring to put on the market only the best possible radio goods. They are endeavoring to produce apparatus that will give the radio enthusiast an outfit that cannot be criticized, so that when he purchases an entire set, or individual parts, he will realize that he is buying tested, standardized merchandise and that he can rely on it as if he were purchasing a phonograph or an automobile.

In view of the possibility of foreign tubes being brought to this country free of duty and competing with the home-manufactured article, RADIO WORLD sought the views of American dealers, whose letters are published herewith:

Would Put Us Out of Business

By J. E. Allison, Secretary, Moorhead Laboratories, San Francisco.

RADIO vacuum-tubes should not be admitted to the United States duty free, for the reason that the production costs in Europe, to-day, are at a low cost

—lower than ever before. Tubes can be manufactured there, shipped here, and distributed with profit, if admitted free of duty, at a price that would paralyze our domestic industry.

Speaking for the Moorhead Laboratories, its plant is equipped with special machinery, devised and built at a heavy cost for the production of vacuum-tubes only, and not suitable for the manufacture of other products. Admitting vacuum tubes to the United States duty free will simply put us out of business.

A tariff, which would force the imported tube to a selling price equal to our own, is due to the men who have devoted much time and money to the evolution and manufacture of the radio tube.

* * *

British Tubes Superior

By M. F. Klicpera, President-Treasurer, Klitzen Radio Mfg. Co., Racine, Wis.

WE feel that vacuum tubes of a foreign nature should be admitted into this country duty free. We understand that most of these tubes are manufactured in England and France, and to our knowledge we know nothing very definite about the German tubes.

However, the British tubes have proven so superior and successful to the American made tubes and also of the extremely low prices at which they are sold, has led us to believe it to be very beneficial to radio trade if these tubes were admitted free. This admission would, no doubt, reflect very strongly on the present prices of vacuum tubes as manufactured in this country.

We firmly believe the prices asked for tubes are beyond reason, and, therefore, a cheaper and better tube would be very heartily welcomed by the radio fraternity without question.

* * *

Foreign Tubes Should Be Admitted

By Paul F. Johnson, Altadena Radio Laboratory, Pasadena, Cal.

WITH the tube situation as it is, we would be in favor of Senator Frelinghuysen's amendment to the tariff bill to admit vacuum tubes free of duty. We do not know anything about tubes coming from Germany but from our knowledge of other things made in England, we believe that the English tubes are undoubtedly good and would be glad to have a chance to try them out in this country.

We believe that the Radio Corporation and General Electric Company are holding up the public on vacuum tubes, selling them at retail prices of \$5 and \$6.50 for tubes that probably do not cost them over 15 cents to make, and which they could sell wholesale at a price of 30 cents or 40 cents and make a big profit. Also, in spite of the fact that they have had all summer to catch up on their orders, we are still short of tubes out here on the Pacific Coast; and when the fall rush starts in, unless a big quantity of tubes arrives pretty quickly, there is going to be just as bad a shortage here as there was last spring. We have been trying all summer to get tubes that were ordered six to

eight months ago and have succeeded in getting only a very small quantity.

If foreign tubes were admitted free of duty, we believe the General Electric Company would have to get a hump on themselves and also put the price down to a reasonable figure.

* * *

Would Benefit User

By P. C. Leffel, Manager, Radio Equipment Company, Springfield, Ohio

WE would like to see the amendment to the tariff bill go through admitting free vacuum tubes, although imported from Germany. It would benefit the user as well as the dealer, from our standpoint of view.

* * *

Detrimental to Radio

By J. C. Hobrecht, J. C. Hobrecht Co., Sacramento, Cal.

IT is the writer's opinion that this (admitting vacuum tubes free of duty) would be absolutely detrimental to the development of radio in this country. The men who have worked to develop American tubes and are putting them on the market are entitled to protection, and in a case of an emergency they are the only ones the country can depend upon. Consequently you can register my opinion as heartily opposed to admitting any tubes duty free.

* * *

There Will Never Be Another Tube Shortage

By an American Tube Manufacturer.

ASK the readers of RADIO WORLD to help support the radio industry of America by writing their particular Senator that the tariff bill should levy a duty on all foreign made radio equipment. You can specifically call their attention to the proposed amendment which would mean that foreign made vacuum tubes would be admitted to the United States duty free. You can appeal to their fairness in supporting the radio industry of this country.

Another point is that purchasers of foreign made equipment will be at a decided disadvantage as regards service or spare parts. I grant that some products are entirely satisfactory when made in foreign countries, but anything as complicated as radio should be manufactured at home to give the best service from all standpoints.

Naval Transmitting Sets for Sale

THREE hundred and ninety-six radio transmitting-sets are being offered for sale by the United States Navy Central Sales Office by sealed bids. These radio transmitting-sets are of short-range type, C W-396, with vacuum tubes man-

ufactured by the Western Electric Company for use on submarine-chasers during the World War.

This apparatus is said to be reliable for radiotelephone communication within a distance of ten miles, but numerous instances have been noted where the sets have been used for distances up to 300 miles at sea. In the hands of competent operators, under favorable weather conditions, they should have a reliable land range of 50 miles.

Purchasers of sets have the right to operate them for any purpose, except where a charge is made, under the Department of Commerce Regulations.

For CORRECT RADIO MAILING LISTS Use THE POCKET LIST

of Radio Manufacturers, Jobbers and Dealers in the United States and Canada. Issued Quarterly—January, April, July and October. October, 1932, issue corrected to September 15th, 1932. Classified under three different headings—Manufacturers, Jobbers and Dealers—and alphabetically arranged by states, cities and towns and names of firms. Containing approximately 15,000 names and addresses.

We have been exceptionally careful to see to it that every Manufacturer, Jobber and Dealer is listed and, under the PROPER CLASSIFICATION. Most mailing list concerns charge more than \$100 for a list of this kind and, as a rule, those supplied are far from being correct. Compare this list with any other, and you will find it to be the very best obtainable anywhere at any price.

October issue ready for distribution September 25th. Price \$5.00 per copy, or \$10.00 per year (four issues, including monthly supplements which keep the list absolutely correct and up to date at all times). October edition limited. Send your order with remittance today.

F. D. PICKENS, 1821 CARRINGTON STREET JANESVILLE, WISCONSIN

A Unique Radio Experience

EDITOR, Radio World: Recently there occurred in the little town of Fairdale, North Dakota, an incident which may be of interest to your readers; and one, which, so far as I know, is unique.

One day, when turning the tuning knob of a small set (tube detector with two-stage amplifier) the operator was surprised to hear telephone conversation over a telephone wire that ran about ten feet below the aerial. Thoroughly surprised, he tore off his head piece and went to his own telephone where he called up the party he had heard and found that the words he heard had just been spoken.

He had the tuning "somewhere in the shortest wave-lengths," when he heard the voices, but has been unable to duplicate the feat. Has anyone else had a similar experience?—Albert Lundberg, Fairdale, North Dakota.

Current Articles on Radio Listed

RADIO enthusiasts who are anxious to keep in touch with current literature on radio developments and news will be able to do so by consulting the list of radio references prepared by the Bureau of Standards and issued monthly in the "Radio Service Bulletin" of the Department of Commerce, Washington, D. C. The list is divided into the following topics: Radio Communication, Principles, Measurement and Standardization, Apparatus and Equipment, Communication Systems, Applications, Stations and Management, Manufacturing, and kindred subjects.

Fire-Prevention Data by Radio

DURING Fire Prevention Week, October 2-9, officials of the National Board of Fire Underwriters have requested broadcasting stations to cooperate in a campaign to stop fires and to generally educate the public in fire prevention. Several broadcasters have already offered their aid. Data concerning fire fighting and fire prevention is being sent to the radio stations, for distribution, by radio.

Park Receiving Stations

WIAY, WOODWARD & LATHROP'S a popular broadcasting station of Washington, D. C., has expanded its service to the public by installing loud speakers in several of the Capital's parks. Hundreds of people assemble on Saturday nights to listen to concerts. Entertainment by radio is thus furnished to many people who do not have receiving sets, and has the advantage of keeping them out in the air while the radio service is on.

Latest broadcasting map 15c. That is, a complete broadcasting map appeared in Radio World, No. 8, dated May 20. Mailed on receipt of 15c. Radio World Company, 1493 Broadway, N. Y. C.

Foreign Inquiries for Radio Apparatus

INQUIRIES are being received at the offices of American Commercial Attache McQueen, Santiago, Chile, regarding the development of radio telephony in the United States. It seems probable that, before long, serious consideration will be given to the exploitation in Chile of this new development. Legislation is now contemplated there based on the laws of the United States, and although it does not provide specifically for broadcasting stations by private enterprises it is possible that this service will be available through the leasing of government-owned stations during times of peace.

If American manufacturers interested in the Chilean market will send catalogues and other descriptive literature to the office of the commercial attache at Santiago, the Department of Commerce states, this literature will be placed at the disposal of all persons inquiring for this type of apparatus. Trade opportunities, during the past week, include inquiries from Czecho-Slovakia as to radio transmission stations. From the Philippine Islands comes a call for information on radio apparatus in general.

American radio exports during July totaled 225,475 pounds of apparatus, valued at \$385,861, which shows that some American exporters are taking advantage of trade opportunities.

Radio Thief Caught by Set in Motor-Car

ONE night last month, the home of Daniel F. Murphy, Cleveland, Ohio, was burglarized and a large part of the equipment of his radio station stolen. Among the loot was a high-powered sending set.

Several days later radio operators in Cleveland heard a new station with powerful apparatus sending out messages. The new station had no call number, was not licensed, and could not be located.

Believing it was operated by the thief who robbed him, Murphy, an electrician, set out to find it. He installed a receiving set on an automobile and night after night toured the city, tuning the set to the pitch of the unknown operator. When the messages grew faint, he changed the direction of the car.

Finally repeated circling of a particular block failed to show any point where the messages could be heard more plainly than at another.

Eric Kutz, 18 years old, lived in this block. He had become the pride of the neighborhood with his new wireless set. Persons came to his home every day to see the set. As fellow radio fans, Mr. Murphy and his friends also visited the house. There they recognized the stolen apparatus.

Radio Courtesy

WOR overstayed their time last Monday evening, thanking WJZ for the latter's courtesy in permitting them to encroach on five or ten minutes of the RCA's schedule. The thanks were sent over the air by WOR's fair announcer with an almost ironic politeness that called to mind the way Carpentier and Dempsey shook hands before the battle.—2 PI, in "The Globe"

Another Epitaph

Sad the tale of mild Ben Meyer, Who tried to fix a call-bell wire; Tapped high voltage to his sorrow; They're grounding Ben, at ten tomorrow. —"Science and Invention."

Points to Remember When Buying Parts

So many thousands of small manufacturing firms sprang into being last winter when the radio excitement was at its height that all of us—fan, amateur and professional—are reaping the sad rewards, says "The Globe," New York. But because of their inexperience the greatest loss falls on the radio fans, particularly those who are just becoming interested in the subject. To this latter class the following points will be of assistance in selecting sets and parts:

Trade only at reputable stores. Buy only reputable goods, preferably those having the name of the maker on them.

Insist on having every part tested before leaving the store. In the case of tubes this means more than merely attaching the proper prongs to a six-volt battery to see that the filament is intact. It means that the tubes should be tried out in a set that is actually in operation.

Arrange with the seller that any parts found unsatisfactory may be exchanged or the amount paid refunded. All stores with a solid backing will readily agree to this.

Don't shop with a dollar in your hand. Watch the quality of the goods. Cheap goods give cheap results, first, last, always. Pay a little more and get the tubes, phones, tuning units and other accessories that have made a name for themselves.

It is dangerous to pay too little for complete sets. Cheap transformers are useless. Poor design is fatal. Disorderly arrangement of parts is sure to prove disappointing. If you buy a complete set, buy one with a confidence that tells you that you will never have to open the cabinet unless you so desire.

Buy a set that you can eventually expand into your ideal outfit, whatever that may be.

And lastly—when you shop—take some one along who knows the game from aerial to variometer. If you do that you can have no regrets.

Ether Wave's Journey to Mars

EDITOR, RADIO WORLD: I wish to call your attention to a slight discrepancy in an article entitled "Radio Travels to Mars," in the September 16th issue of RADIO WORLD. To quote from the article: "Every ether wave that leaves the earth touches Mars a few months later." Radio waves travel at the rate of 186,000 miles per second. As there are 2,592,000 seconds in one month (30 days), if it took even that long for a wave to reach Mars, that planet would be placed at the tremendous distance of 482,112,000,000 miles from the earth. As a matter of fact, Mars is, approximately, 44,000,000 miles away, and would be reached by a radio wave in a trifle over four minutes. A wave reaches the moon, which is 240,000 miles away, in about 1 1/4 seconds. The wave reaches Neptune, the most distant of all the planets, in less than four hours.

I noticed in the same issue of RADIO WORLD an article based upon the work of our own school on this station; and as we all like publicity, I was very much interested.—Henry Hall, Squadron III, Naval Air Station, Pensacola, Florida.

A Radio Necessity!

**COMPLETE
LOUD
SPEAKER**

**A QUALITY
PRODUCT**

*At the price of a
high grade headset*

With a SPIROLA CONCERT you can sell your headset—you won't need it even for tuning in the distant stations. SPIROLA CONCERT is so sensitive to weak signals that it is even better for this purpose than the ordinary headset—and everybody can share the fun of "picking up" new stations. We have picked up five hundred mile stations more than a thousand miles away in this manner, using two stages of audio amplification and the loud speaker alone.

We have heard a thousand mile station twelve hundred and fifty miles a way loud enough to hear clearly through several good sized rooms.

And at the same time SPIROLA CONCERT brings in the nearer stations with all the loudness you could wish

and as clear and natural as life itself.

Cabinet type with a special loud speaking unit built into it as an integral part—complete with cord, ready to hook in, in the same way as a headset. No exciting battery or extras required. Beautiful mahogany or dark oak finish, bronzed throat, at dealers or prepaid direct..... **\$12.50**

Guarantee—if you wish to return your SPIROLA for any reason whatsoever do so within ten days and your money will be immediately refunded.

Radio Activity Booms Copper and Brass Business

LARGE demands are reported by manufacturers of copper wire, sheet, tube, and bar stock for copper in one form or another for use in radio apparatus. This statement, and the following, is taken from a bulletin issued by the Copper and Brass Research Association.

There is not a single instrument of a radio sending or receiving set but what requires copper, brass, or bronze in its construction. The high electrical conductivity of copper makes it absolutely essential for all switches and parts using wire to convey the delicate electrical impulses received from the air. Brass, because of the ease with which it can be machined, is largely used for binding posts, plugs, audion bulb bases, and the like. Where unusual strength is a requirement, phosphor or silicon bronze finds wide application.

Sheet copper and brass are used in construction of the adjustable condensers that assist in increasing the strength of the electrical impulses. From one to three condensers of ten to thirty plates each are necessary to the average amateur receiving station. The plates are semi-circular in shape, with a diameter of four to five inches and .025 inch thick.

Perhaps copper's greatest usefulness in radio telephony, however, is in antennae or aerials for intercepting the electrical impulses transmitted from one station to another. And probably in no other commercial application is copper called upon to stand up under such severe conditions as are found in antennae service. It must resist the corrosive action due to varying climatic conditions, and must have sufficient strength to withstand the strains due to wind pressure and its own weight when suspended in long spans.

Most radio engineers have come to agree that for short span aerials the most satisfactory material is No. 14 or No. 16 bare copper wire. Experiments conducted by the U. S. Bureau of Standards have led to the same conclusion. Furthermore, the slight difference in first cost is more than offset by copper's uniform, lasting service.

For large antenna, phosphor bronze stranded wire has given most satisfactory service, the best size being seven strands of No. 20 or 22, providing a larger copper service for catching the electrical waves in the ether. Another advantage of this kind of aerial lies in the fact that, due to its stranded construction, this form of aerial absorbs considerable stress before the metal itself begins to stretch.

Pictures and Facts About Armstrong Amplifier

Radio World has published a number of pictures, diagrams and descriptive articles regarding the New Armstrong Super-Regenerative Amplifier. The numbers containing this material are dated June 24, July 8, July 15, August 5 and September 16. They will be sent postpaid on receipt of 15 cents each, the five copies complete for 75 cents. Or you can subscribe, \$6.00 year; \$3.00, six months, and have your subscription start with the number dated June 24. RADIO WORLD CO., 1493 Broadway, New York.

Important Change in Second District Radio Schedule

A NEW schedule for broadcasters in the Second Radio District, New York, is now in effect. The new programme has been arranged to eliminate interference so far as is possible:

The management of WJZ had the privilege of broadcasting on 360 meters, sharing the time with the less powerful stations, or going in with the Class B, the most powerful stations in the Second District, and operating on 400 meters.

The Class A stations agreed to stand by on special occasions should WJZ, the Radio Corporation-Westinghouse station at Newark, N. J., want to broadcast concerts, such as the Stadium Concerts given by the Philharmonic Orchestra; play by play results of the World's Series, and the Saturday afternoon football, also, to permit WJZ to broadcast every evening.

Class A stations are: WWZ, John Wanamaker, New York; WBS, D. W. May, Newark, N. J.; WHN, Ridgewood Times, Ridgewood, L. I.; WRW, Koenig Bros., Tarrytown, N. Y.; WBAN, Wireless Telephone Company, Paterson, N. J.; WAAT, Jersey Review, Jersey City, N. J.; WAAM, I. R. Nelson Company, Newark; and WFAF, Shotton Electric Company, Poughkeepsie, N. Y.

WJZ will continue to operate on the 360 meter wave length. As usual, the bedtime stories will be broadcast every evening from 7 to 7:30 P. M. by WJZ. This station will then stand by for an hour on Monday, Thursday and Friday and Saturday evenings and for an hour and a half on Tuesday and Wednesday evenings for the other members of Class A stations.

Class B stations of the Second District, New York, are supposed to keep up a continuous daytime and evening programme on 400 meters.

At present the programmes for Class B stations are not complete. Class B members are: WOR, Bamberger & Co., Newark, N. J.; WGY, General Electric Company, Schenectady, N. Y.; WHAZ, Rensselaer Polytechnic School; WBAY, American Telephone and Telegraph Company, New York.

The proposed arrangement will provide continuous entertainment on two separate and distinct wave lengths from 8 A. M. until 11 P. M.; and 400 meters, sometimes, until midnight.

Radio Operator Lost! Will Radio Find Him?

J. RAY ATKINS, a radio operator, last heard from a year and a half ago on board the steamer "Bellemina," on the New York-Argentine run, is sought by his mother, Mrs. J. R. Atkins, Box 253, Midlothian, Texas. In the hope that some of his brother operators may know where the missing young man is, or that he may be located by means of radio itself through broadcasting, the Department of commerce is asking that his story be carried in both the press and in the ether.

Junius Ray Atkins served as a sergeant, first class, in Company A, 111th Field Signal Battalion of the 36th Division, during the World War. He returned to this country on June 4, 1919, and was discharged at Camp Mills. On July 14, 1919, he secured a first-grade radio operator's license, which expired in August, 1921, but was not renewed. Later, he was a ship wireless operator. He is twenty-three years old and a native of Midlothian, Texas, where his father is principal of the high school.

Subscribe for Radio World, \$6.00 a year, \$3.00 six months, \$1.50 three months.

IMPORTANT NOTICE:

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

New Office Building to Be Wired for Radio

FOR the first time in the history of Pacific-coast office-building construction, a 15-story skyscraper in San Francisco, erected by a navigation company, will be wired throughout for radiophone installation, says "Popular Mechanics." Tenants wishing to put in a receiving set will only have to "plug in" to a wall socket, as for a desk lamp, to be connected with the antenna on the roof and receive broadcasting programs from stations in San Francisco and vicinity. Not only will the new building be completely wired as a convenience to tenants who are radiophone enthusiasts, but the company intends to install a powerful sending and receiving set, with which it is expected it will be possible to give orders to the captains of the company's nine freight and passenger ships, which maintain a weekly service between San Francisco and the Hawaiian Islands.

British Radio Situation

BRITISH manufacturers appear determined to keep the products of Yankee manufacturers out of their country, says "The Mail," New York. No one will suffer thereby except the English public. They will be denied reasonably priced apparatus that will perform more efficiently than the products of their own manufacturers. We have been manufacturing amateur apparatus for many years and the experience we have gained not only makes it possible to produce reliable apparatus at reasonable prices, but puts our production at a point where it will take foreign competitors many years to reach. England, however, is going to do much better than we have done on one thing. Their broadcasting will be done systematically from the very start. Who wouldn't start systematically after having had the opportunity of witnessing the terrible mess we have made of broadcasting? However, we can overlook our blunders, since they were characteristically Yankee.

Weekly paper wants circulation and subscription manager with ideas and experience. Address by letter, R. W., room 326, 1493 Broadway, New York City.

MOULDED COMPOSITION binding posts, 8c. each; 90c. dozen. Fixed phone and grid condensers, 15c. each. No stamps. F. A. Keeler, 912 Harrison Ave., Boston, Mass.

50-V.T. HOOK-UPS. Largest collection of diagrams for radio receiving circuits published. Includes latest in radio frequency and super-regeneration. Loose-leaf form complete with binder. Prompt deliveries. Postpaid, one dollar. W. A. Dickson, 409 East Fort St., Detroit, Mich.

FOR SALE—Regenerative sets with detector. Complete with tube and B Battery, \$35.00. With one stage, \$50.00, complete with tubes and batteries. Satisfaction guaranteed. Edward Bittner, Schuyler, Nebraska.

Exchange jolly interesting letters through our Club! Stamp appreciated. Betty Lee, 4254 Broadway, New York City.

\$1.00 RADIO FREQUENCY TRANSFORMERS—Hear distant stations. Designed to fit any standard socket. Three sizes, 160-500M; 500-1000M; 1000-2000M. Complete set of parts and full directions for assembling, postpaid, \$1.00. 3 for \$2.75; 6 for \$5.00. Arkenberg Agency, 702M, World Bldg., New York City.

DO YOU USE A CRYSTAL DETECTOR? ARE YOU MAKING A CRYSTAL RECEIVER? Increase the efficiency of your crystal detector 1,000 per cent by using a "PT" Ultra-Sensitive Contact. Of special gauge and alloy. Makes and holds a quick, ultra-sensitive, stable adjustment. Using galena, you may pound panel or table without disturbing sensitivity in slightest. Proved practical on shipboard by an old-time Marconi operator. Using a "PT" Contact on galena, Arlington (NAA) was brought in clear at 3,300 miles (below the Equator); and Arlington came in loud at 2,200 miles (off Dutch Guiana). In both instances, nearby ships using vacuum tubes were unable even to hear NAA. As to stability, Cape May (WCY) was worked over 1,000 miles, sending right through crystal with 2 KW spark, without affecting detector's adjustment. Replace your old insensitive unstable contact with one which will hold its adjustment in addition to giving louder signals and music. Indispensable for pocket sets and crystal detector-bulb amplifier outfits. A novice can install. "PT" Ultra-Sensitive Detector Contact, with instructions, twenty-five cents coin or M. O. "PT" CRYSTAL CONTACT CO., Box 1641, Boston 8, Massachusetts.

Answers to Readers

RECENTLY we installed a radio set about 20 feet from the power lines of a nearby railway. We have a 4-wire inverted L aerial. Each one of these wires is 50 feet long. We also tried an inside aerial, about 100 feet long, but are unable to stop the machine-gun effect coming from the power wires. Is any way by which this interference may be eliminated?—John Hoffman, Phoenix, Arizona.

The best way to achieve your object is to place the aerial at right angles to the power lines of the railroad. If this means that you are compelled to place the aerial so that it becomes anti-directional with the broadcasting stations, then we suggest that you make

a T-type aerial of your present system. A single-wire aerial would be far better than your 4-wire aerial.

I have a regenerative coil using a tickler. I do not experience any results. Please publish a hook-up of the connections.—James Wildflower, Toledo, Ohio.

Hook-up requested by James Wildflower, Toledo, Ohio.

A diagram is herewith shown of the proper connections for a regenerative set employing the tickler coil.

I have a short-wave regenerative set, including 2 variometers and 1 vario-coupler, using a radiotron UV 200 and UV 201 as an amplifier. I don't seem to hear any signals and believe something is wrong. Could you offer me any such suggestions to remedy my trouble?—Arthur Olsen, Brooklyn.

Assuming that all your connections are correct, it would seem that the trouble lies

in wrong polarity. Reverse your plate-B battery and see if any change develops. All you need to do is join the positive pole of the B battery to the plate of the tube. The negative terminal, of course, is joined back to the storage battery. If you do not get any results, simply reverse the negative of the B battery on the negative of the storage. Your trouble lies there.

Regarding the Armstrong superregenerative amplifier, are the honeycomb coils right for the millihenry choke coils and in what position should they be. Can duo-lateral coil, No. 400, be used for the coil L-4. What is the constant for the phone fixed condenser?—Morris Siegel, Mahopac, N. Y.

You may use the 400 turn duo-lateral coils for the 10 millihenries high-frequency choke. The coil you mention may be used. The capacity of this condenser should be .0025 mfd.

Should I use a soft tube or hard tube in the detector step of a two-stage amplifier? Where are stations WLAW and WEAM?—Michael Brody, Springfield, Mass.

Use a soft tube for the detector and hard tubes for the amplifiers. WEAM is located in North Plainfield, N. J. WLAW is the new police broadcasting station, New York City.

My aerial is a single wire, 85 feet long, having 35-foot lead-in. Is a single wire, 150 feet long, better than a two-wire, 75-foot aerial. With my present aerial, signals seem to come in loud from one direction. Why is this?—Arthur Swenson, Brooklyn, N. Y.

Would suggest that you erect the one-wire aerial, 150 feet long, in preference to the two-wire. The reason your signals come in loud from one direction proves that you have a directional antenna. This is accomplished by the end the lead-on is taken from. If you change your lead-in wire to the other end, then signals from that direction will come in loud.

Trying to "Raise" Us

AT WGI last night the radio program began with a Sleepytime Story. Next was "Banking," by Frederick W. Sleeper, and then came "Making Use of Last Year's Clothing," by Miss Harriet E. Ainsworth. If the radio fans listening in on WGI had a wakeful night after that, let them consult physicians, suggests the critical and observing F. P. A., in "The World," New York.

A Southern contemporary says it would like to hear broadcast the news of the execution of the "inventor of white socks." Perhaps he would be more satisfied if he saw the event.

The Houston "Post" has invented this joke:

"Why was it that George Washington never told a lie, Pa?"

Because he was never asked if he picked up a 1450-meter wave.

"If you would care to speak," the latter goes on, "or broadcast some of your material through the air—Enough. Here is some humorous material:

I read this poem into the air
And it was broadcast everywhere;
It didn't have much sense or wit,
But the Westinghouse people wouldn't pay for it.

A Sunday-supplement scribe on "The World," New York, brought his editor the following:

"Oh, mother, listen to the radio!" cried a small boy in the B. R. T. subway train. He had heard the voice from the electric announcer at the end of the car.

"The radio religious service will never be popular," the Washington "News" observes, "because the women can't see each others' hats."

And now, I suppose, aviators and submarine commanders and radio fans will bawl each other out in the new realms. What will happen when the day comes that we all carry an instrument in our pockets by which we can read everybody's thoughts? "So that's what you're thinking, is it?" a stranger may say to you—and punch you in the eye.—Bruno Lessing.

Farewell, Static!

GOOD-BY, static,
We speed you on your way.
So long, static;

We would not have you stay.
The summer's gone, the autumn's here;
No more your noises, many, queer,
Will break in on our evening cheer—
So on your way; move fast, old dear.

Good-by, static;
You sure have had your fun.
So long, static;

Your dirty work you've done.
You've spluttered, hissed, and filled our set
With wild, unearthly sounds, and yet
We'll miss you. Are we glad? Just let
Us say we are—you bet, YOU BET!

—H.

Necessary Parts for a Short-Wave Receiver

See page 13 for hook-up and description

RAUDIO has been surrounded by so much mystery that thousands of enthusiasts have been misinformed. The information gathered has led many to expect results from their receiving sets which should not have been anticipated. For this reason, the half-tones herewith presented show the necessary instruments the average amateur will need in making up a short-wave receiver. If assembled correctly this receiver should pick up broadcast matter over a considerable distance. It is the part of a set which makes up the Armstrong regenerative circuit. The upper half-tone shows a back and rear view of the parts needed, such as the two variometers and the tapped vario-coupler. The half-tone to the right is that of the vario-coupler, showing the method used in soldering the leads of the taps of the primary to the contact points, which are fastened to the outside panel. The regenerative receiver, using such variometers, has come into common use in the reception of both radiophone and radio-telegraph communication, and the added increase in strength of signals makes it possible for this type receiver to catch very weak signals from exceedingly far distances. In other forms of receivers, amplifying tubes are required to increase the loudness of the signals. A common type of regenerative receiver with a complete diagram using

these instruments is published on page 13 of this issue, together with an article entitled, "A Regenerative V.-T. Receiver for Short Waves," by Fred Chas. Ehlert.

MICROSTAT VERNIER RHEOSTAT

The most sensitive filament control and quickest, easiest tuned. This microstat has ten times the possibility of exact filament adjustment as over the ordinary wire rheostat.

It eliminates grating and interfering noises, has single knob adjustment and is far more durable being made of better material with greater care.

This microstat takes up less room on the radio board, is neat and compact. The exact calibrations of the microstat are due to the gradual entering of two points into the resistance material of our own composition which gives us exacting and most minute measurement of current to the filament as the operator brings the two points together or separates them through the screw handle.

Order through your dealer or delivered to any part of U. S. **\$1.40**

Radio Adds Interest to World's Series

(C. Underwood & Underwood, N. Y.)

MORE people were in touch with the World's Series, at the Polo Grounds, New York City, this year than ever before in the history of the great American baseball classic—the one sporting event dear to the heart of every citizen. And radio was responsible, because, by radio, the news of each play made was immediately broadcast all over the American continent and far out to sea. Even in out-of-the-way hamlets, where, in other years, people had to await the arrival of a week-old newspaper, the news came through and each play was described almost as quickly as it was made. In the upper half-tone you will see George Kelly, first baseman of the Giants, trying out the transmitter by which the news was sent to WJZ, Newark, to be broadcast. The lower half-tone is a splendid view of the radio section of the press box, showing the baseball expert writer, and radio operator at work. A notable radio service was conducted by Grantland Rice, baseball expert of "The Tribune," New York. Through his paper, the games were broadcast, and, it is reported, the news was picked up as far north as Quebec. Though the weather was unusually warm for October, many feared that there would be an unusual amount of static interference; but, from all reports, the broadcasting came through unusually clear. WJZ has received many letters attesting this. It is reported that next season the Polo Grounds will be equipped with its own transmitting apparatus.

(C. Fotograms, N. Y.)

Using the Vario-coupler in a Short-Wave Regenerative Set

By George W. May, R. E.

Primary of the Vario-Coupler.

FOR receiving short-wave lengths up to 600 meters, the circuit employing the grid and plate variometers is the most popular. This circuit has been in use for a long time. Such a set will be found in nearly every amateur station. To the novice the different circuits used at present are more or less confusing, and it is hard to pick out the most satisfactory. For best results on most wave lengths, duo-lateral coils are hard to beat; but the set described in this article is best for short-wave lengths. For broadcasting, as it is operated at present, this circuit cannot be surpassed.

The parts may be purchased or may be built at home. Two variometers will be needed, also a vario-coupler. As variometers are cheap enough to buy we will only describe the making of the coupler and the wiring of the set.

The inductive tuner used in short-wave regenerative sets is sometimes called the vario-coupler. The distinctive features of the vario-coupler are the use of the rotor for the secondary, which is placed in the field of the primary, and the use of the untapped secondary-winding. The rotor, which is frequently in the shape of a ball, is made to revolve through 90 degrees to change the coupling between the primary and the secondary circuits.

The primary of the vario-coupler is made of a tube, or cardboard, about 3½ inches long and about 4 inches high. It is then wound with about 64 turns of No. 22 double cotton-covered wire in one layer. The winding is tapped every 10th turn starting from 1, 10, 20, 30, 40, 50, and then every 2 turns thereafter. This will give a tap for every 10 turns and every 2 turns. Thus there are 5 ten-

turns and 7 unit turns. The tapping wants to be diagonal along the tube to prevent short circuiting. It will be easier to make the connections of the primary to the taps on the panel. A ¼-inch hole is drilled about the secondary shaft-bearing. It should be ½-inch from the top, in such manner that it will be concentric to the primary and not rub against the sides.

The secondary consists of a piece of tubing about 1½ inches long and of such diameter as to allow it to rotate freely within the primary tube. A piece of tubing about 2½ inches long will do. It is wound with about 52 turns of No. 24 double cotton-covered wire in 2 equal sections separated by about ¼ inch. A ¼-inch shaft is

Secondary of the Vario-Coupler.

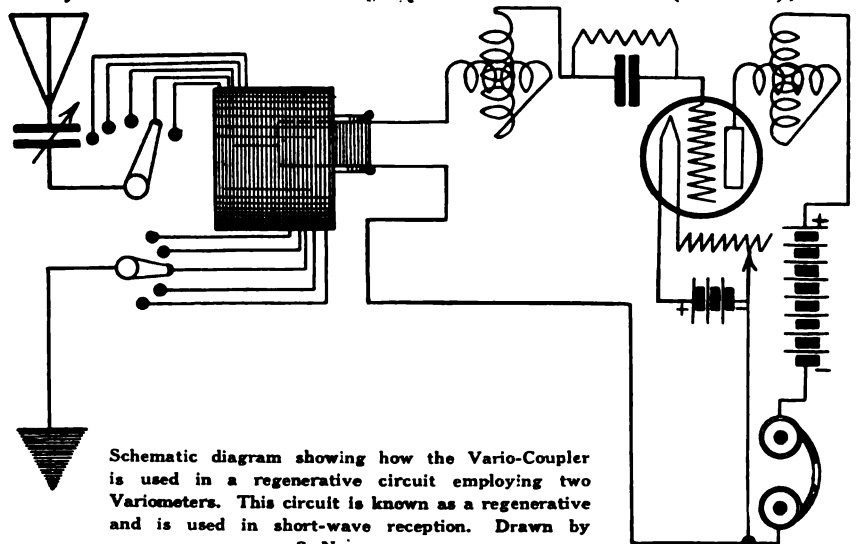

fitted to the secondary tube and made fast with lock nuts. The shaft projects through a hole and made to turn freely. Two flexible cords, or wires, are fastened to the secondary leads to provide for connection in the circuit. Enough slack must be allowed so the coil can rotate without injury of breaking the windings or leads from the secondary.

Schematic diagram of the top of the primary of the Vario-Coupler, Ground and Aerial connection.

This vario-coupler may be mounted on a bakelite panel with knobs and taps for adjusting the instruments. The tapping process is very simple, as the wire is wound to keep track of the number of turns. Bring each 10th turn out and solder a wire from the tap to the contact point on the panel. This process must be carried out on all the taps, including the unit taps, care being taken to get the right taps on the right contact points.

In wiring up the set, what is needed first is a piece of bakelite panel, two variometers, one grid leak and condenser, one tube (detector), one B-

Schematic diagram showing how the Vario-Coupler is used in a regenerative circuit employing two Variometers. This circuit is known as a regenerative and is used in short-wave reception. Drawn by S. Newman.

First Alaska Broadcaster Is WLAY

13 Class A Stations and 11 of the New Class B Stations Makes Grand Total of 534

THIRTEEN regular broadcasting licenses, now known as Class "A," were issued by the Department of Commerce during the week which ended September 30. Among them is the license for the first broadcasting station in Alaska, WLAY. This is the station of the Northern Commercial Company, located at Fairbanks, nearly in the center of that territory. It will broadcast a program of entertainment for the benefit of those living within a radius of about 500 miles.

The following are the Class A stations in this issue:

WLAV—Electric Shop, Inc., Pensacola, Fla.

WNAF—Enid Radio Distributing Co., Enid, Okla.

WOAA—Dr. Walter Hardy, Ardmore, Okla.

WLAZ—Hutton & Jones Electric Co., Warren, Ohio.

WOAE—Medland College, Fremont, Neb.

WLAY—Northern Commercial Company of Alaska, Fairbanks, Alaska.

WMAK—Norton Laboratories, Lockport, N. Y.

WNAD—Oklahoma Radio Eng. Co., Norman, Okla.

By Carl H. Butman

WNAB—Park City Daily News, Bowling Green, Ky.

WMAL—Trenton Hardware Co., Trenton, N. J.

WMAP—Utility Battery Service, Easton, Pa.

WLAW—New York Police Department, New York City.

WNAH—Wilkes Barre Radio Repair Shop, Wilkes Barre, Pa.

During the week which ended September 30, the Department of Commerce licensed 11 broadcasting stations in the new Class "B." This is the first issuance of the new licenses to the superbroadcasters, and celebrates the licensing of the first broadcasters a year ago. All of the stations licensed under the new regulations are old ones which have been listed under limited commercial stations engaged in broadcasting for some time. They comprise large stations which have qualified with the rigid requirements of the department and are now entitled to use the special 400-meter wave length assigned exclusively to these stations. Only high-class entertainment will be carried; mechanical music is forbidden. The stations

which remains in Class A, over 500, are permitted to broadcast "canned" music if they desire.

Among the B stations are the well-known calls of Westinghouse, General Electric, Western Electric, the A. T. & T. Company, and such papers as the "Detroit News," "St. Louis Post Dispatch" and "Dallas News."

The first Class B list follows:

WFAA—A. H. Belo & Co., "Dallas News," Dallas, Texas.

WBAY—American Telephone & Telegraph Co., New York.

WOR—Bamberger, L. & Co., Newark, N. J.

WWJ—Evening News Association, "Detroit News," Detroit, Mich.

WGY—General Electric Co., Schenectady, N. Y.

KSD—Pulitzer Publishing Co., St. Louis, Mo.

WHAZ—Rensselaer Polytechnic Institute, Troy, N. Y.

WOO—John Wanamaker, Philadelphia, Pa.

WEAF—Western Electric Co., York.

KYW—Westinghouse Electric and Mfg. Co., Chicago.

WCX—"Detroit Free Press," Detroit, Mich.

The grand total is now 534.

(Continued from preceding page)

battery (22 volts variable), one pair telephones, one storage battery, aerial and ground. The accompanying diagram shows the internal wiring of the set and should be so wired. One variometer is placed in the grid circuit and the other in the plate circuit. Arrange the panel in such a way that the tube, socket, and rheostat are located in one end and the vario-coupler in the middle, with the variometers, one on each side. Before attaching any of the wires, lay out the work carefully. Be particularly careful to keep all the wires as short as possible. Remember that every bit of wire added makes just so much more resistance to the set and will cut down the signal strength.

The lead wires from the primary taps to the contact taps on the panel should be covered with "spaghetti." This prevents howling and squealing if amplifiers should be added to the set.

By doing this it will also lessen the danger of getting the B-battery through the filament by short circuit from some of these wires.

"Two on the Aisle!" by Radio

(C. Central News Photo Service)

Miss Lillian MacKenzie in the box office of the Globe Theatre, New York, where radio has been installed and reservations may be made by means of the receiving set. Passengers on incoming liners can comfortably engage seats for their first evening on Broadway, and isolated suburbanites may reserve tickets with ease.

Neat Home-Made Tube Socket

By Gordon S. Arthur

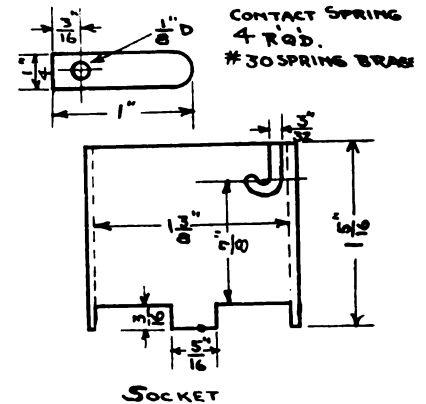

Assembly drawing (full size) emphasizing the neatness and compactness of this socket.

It happens frequently that defects in tube sockets drive many amateurs to making their own. Sometimes porcelain sockets crack and break, while bakelite, or hard rubber, softens and gets out of shape when subjected to the heat of C-W transmission. The drawings accompanying this article show the detailed construction of a neat and compact tube-socket. It has been made and operated successfully. The dimensions given provide sufficient clearance between the binding posts and the socket to prevent short circuits. Many amateurs may wish to enlarge the base so that there will be more room for making connections. This, of course, is permissible since it does not effect the important dimensions of fitting the tube base into the socket.

The cylindrical tubing that forms the upright of the complete socket may be of brass, aluminum, or any other metal that may be available.

BASE

SOCKET

Scale drawings for making tube socket described in this article.

It should be about 1/16 of an inch thick and 1 and 13/32 inside diameter. The contact fingers, of which 4 are required, must be of thin spring brass and cut accurately to dimensions. The base may be of hard wood, fiber, bakelite, hard rub-

ber, or any other insulator. Make it about 1/8 inch thick. The position of the slot in the tube must be so effected that when the bulb is in place the 4 little projecting lugs on the base of the bulb make contact with the proper contact-spring.

Radio Facts

THE reason that dials cannot be calibrated on wave lengths is because different users have to erect different types of aerials of different lengths, and all this affects the tuning of the receiver.

Always remember that when there is more than one tuned circuit, each circuit must be equally tuned to secure resonance or equilibrium. Many who have receiving sets containing two or more circuits simply put a loading coil in the primary circuit and then wonder why they do not get results.

A vacuum-tube receiver is not necessary to obtain the time service of Arlington. A crystal detector, especially a piece of galena, will pick the signals up several hundred miles distant from Washington.

To understand the language of high-powered Hertzian waves it is necessary for the operator to be familiar with the code. The radio alphabet can best be mastered by practicing on some instrument which will emit dots and dashes similar to those formed by the regular radio transmitter.

(Thomas, in the Detroit "News")

MANDY SPOILS A GOOD JAZZ CONCERT
(Washington "Star")

Crystals May Yet Be Best for Receiving

RADIO is now in a stage where owners of sets are not satisfied with some of the local broadcasting, but are diligently moving their dials and adding more equipment in hope of bringing in the so-called long-distance broadcasting stations. More often, the only portions that are heard are the call letters and the signing-off data. But what else goes with this tuning may be mentioned only by the owner himself, with its hissing, howling, and rearrangement of batteries and connections.

Radio this year is in the same condition as last, particularly in regard to creating long-distance reception of phone. Being a new instrument, we have realized its delights and enjoyed the entertainment it has produced; and as soon as fans learn that the long-distance records are being accomplished by most everyone, the idea will soon fall by the wayside. When this happens, the crystal-detector sets will either be used alone or in conjunction with the vacuum-tube amplifiers as a means of amplification. It may be said that a crystal is the only detecting device that will receive the phone without distortion during its action. Whatever the sounds may be, instrumental or vocal, the crystal does not become paralyzed or get out of order. A good crystal-detector once set works alone, unaided by batteries.

Crystal sets have a range from 25 to 30 miles to depend on. If the radio-broadcasting stations are to remain where they are for some months to come, every receiving set will be within range of one of them.

Radio Knowledge Greater Than Instinct

NO less an authority than Dr. C. P. Steinmetz, America's foremost scientist, stated these facts recently in a public address, and gave it as his opinion that an antenna was a safeguard rather than a liability in case of electrical storms. Those of you who feel timid when storms are in the vicinity might well remember that Dr. Steinmetz' *knowledge* is more likely to be correct than your *instinct*. Even if these other stations are on exactly the same wave length as the one you are hearing, they will cause no signal at all to be received. You see, of course, that in localities where there are many stations, this ability to select to some extent the station you want to hear may be very useful.

This Long-distance Regenerative Set Was Made for \$27.80

(Both photographs C. Kadel & Herbert News Photos.)

With the many types of receiving sets now on the market, it would be impossible to give precise directions regarding the building and operation of each. However, vacuum-tube receiving sets come under a general head, so that broad instructions on each class are certain to fit each individual case with due allowance for the peculiarities of each particular set. The use of the regenerative arrangement complicates the operation of a set not a little; but it also makes for louder signals that could not be obtained with a simple circuit. Regeneration is obtained by either the tickler coil or by a grid and plate variometer. Such a set is shown in the above half-tone. The upper half-tone is from a photograph of Mr. Samuel Lebowitz, working on a set that he constructed for only \$27.80. He is shown making some soldering connections on his amplifier section. Note the two variometers with the variocoupler in the center of the photograph. The half-tone at the bottom is the front of the panel.

Vessels Now Guided Through Fog by New System of Radiotelegraphy

By Ortherus Gordon

Figure 1.—When a ship is directly over the radio-piloting cable, the waves strike both collector coils with the same force and effect. The slanting line is the cable from Fort Lafayette to Ambrose Lightship. Drawn by S. Newman.

FOR more than two years, the aids to navigation on the surface of the Ambrose Channel fairway, in the harbor of New York, have been supplemented by a radio-piloting cable. It is submerged and in construction is similar to trans-Atlantic cables, excepting that it is thinner and has only a moderate number of strands. It follows the course of the ship channel for twenty miles, from Fort Lafayette at the Narrows to the outer buoy near Ambrose Lightship; and this fact, together with its name, "radio-piloting cable," gives some indication of the purpose for which it was designed and laid.

Having perfected a system of radio-compass stations whereby a ship approaching any port on the Atlantic or Pacific seaboard, in a fog, may safely pick up the light vessel, or buoy, at the harbor's entrance, the United States Navy Department turned its attention to continuing that service right up the bays and into the basins or docks. It was not enough that a ship should be guided to the outer entrance of the harbor. That ended her navigational difficulties, to be sure; but it did not get the vessel to a dock, where her passengers and valuable cargo might be discharged. It often happened that all the time saved in making the channel entrance by means of the radio compass was lost in waiting for fog to lift so that the ship might proceed up the harbor to the docks. Time is valuable where steamships are concerned. Delay means not a few hundred dollars a day, but thousands of dollars an hour, according to the size of the ship and the demand for her services.

Perhaps the success of the submarine-signalling devices now employed on all vessels suggested the use of a submerged piloting-cable. By means

of two microphones placed in a vessel's forward hold, below the waterline and on the outer shell of the ship on each side, the navigator in the chartroom with headphones on, can hear the distinctive underwater signals of certain lighthouses, sometimes for as much as fifteen miles. Not only that, but by switching from one microphone to the other, he could determine the direction from which the sound waves were coming and steer his ship accordingly.

This is the successful principle of submarine, or submerged, signaling. A device placed at strategic points for transmitting sound waves, and the ship has "ears" to catch them. Why not an electrified cable along the channel course, with suitable ears on the ship for detecting the impulses sent out by that cable?

The suggestion was seized upon and carried out. Experimenting took place at New London, Connecticut, and the project declared practicable. At once the Navy Department proceeded to larger experimentation in New York Harbor. The cable was laid and the tug, "Algorma," fitted with "collector coils" which were to serve as "ears." The inner end of the cable was brought into Fort Lafayette and attached to the apparatus for producing the buzzer impulses sent out on this new form of transmitter. A flow of three amperes was found ample for practical purposes.

On board the ship, the collector coils were placed on each side of the vessel at an equal distance from the 'midship lines. They consisted of from 400 to 800 turns of insulated wire, it having been demonstrated in the preliminary tests that the number of turns directly affected the audibility of the signals received. There must be a rigid sameness about the coils, and all wires leading to and from them must be identically placed in relation to the central position of the headphones. In other words, the effective electrical constant must be the same. On this depends the accuracy with which the path of the submerged cable may be followed, since the guiding instinct is derived from comparing the strength of the signals as caught by the extended ears.

If a tuner is used; that is, if the collector coils are employed as antennas and supplemented by a resonance receiving-circuit, the efficiency of the outfit is increased a thousandfold. For such work as this system will be called upon to perform for the present, tuned circuits, while desirable, are not necessary.

Figure 2.—When a ship is out of the channel and off her course, the collector coils on the side furthest from the cable receive little or no excitement; while the other one gets an overdose. The difference in intensity warns the helmsman, who brings the ship back on her course. The slanting line is the cable from Fort Lafayette to Ambrose Channel Lightship. Drawn by S. Newman.

The ears may be placed above or under water—no difference is noted in the result. It is probable that they will eventually take their place in the bows of the vessel, alongside the microphones of the submarine bell and whistling device. In that position they will reduce to a minimum the distortion due to the shielding effect of the ship's hull.

In the pilot house, the radio helmsman stands at the wheel, headphones on his ears. The left ear-piece is connected with the coil and circuit on the port side of the vessel; the right is connected with that of the starboard side. The man who actually steers the vessel may be an "old salt" unacquainted with the mysteries of wireless, or a high-strung radio engineer with little or no knowledge of ships. If he can hear, and has intelligence enough to distinguish between varying sound intensities, then he can guide a vessel along the path of the radio cable without training or experience. All he must do is to keep the "hum" in his left ear equal to that in his right. He might be blinded, and the bridge blanked off by canvas screens, yet the ship would faithfully make her way through the fog which hangs between her and a journey's end.

To one familiar with the elementary theories of radiotelegraphy, the principle upon which the success of the cable depends is readily understandable. The Hertzian waves emanate from the cable in concentric circles, growing larger and larger as they move away from it. A ship directly over the cable, as in Figure 1, cuts these waves into exact halves, so that the "collector coils" on either side of

What Makes the Radio Receiver Work

By Donald Van Wyck

WIRELESS receivers are made in various forms and designated as single, bi-polar, and watch-case. In radio the watch-case receiver is used exclusively. Usually two of these receivers are placed on a head band and made to fit the head. The complete article is termed a head set. As these head phones, or receivers, must respond to very weak signals they must be made with very light diaphragms and wound with copper wire. Now, if the cap of the receiver is unscrewed, a thin piece of metal, known as the diaphragm, will be noticed. It is held by magnetism. This diaphragm may be taken off; but be careful not to bend it. Under the metal diaphragm are usually two electromagnets, or permanent magnets, with steel cores. On these magnets are wound many turns of copper wire. Both ends of the magnets are termed "poles." One is the north pole; the other, the south pole. The names are used so any person may understand the direction in which the respective poles would be attracted if the magnet were free to swing like a magnetic compass. If a piece of iron is brought into proximity with these poles, it will be attracted. Whenever current passes through such a coil, it becomes a magnet and attracts pieces of iron. The fact that the magnetic pull is present only when the current is on makes the device a very useful one for changing electrical energy into mechanical energy. These coils are seen everywhere in electricity—in door bells, relays, alarms, and telegraph sounders used in telegraph offices.

In the telephone receiver, these magnets are mounted, one each, on the ends of the permanent steel-magnets. With this arrangement, the magnetism from the permanent magnets is carried up through the iron in the coils so that

(Continued from preceding page)

the vessel receive signals of equal strength. This is the navigating position of the vessel, and the one continually sought for as the ship veers from side to side.

As this veering there is a noticeable increase in the strength of the signals in one ear-piece and a corresponding decrease in the other. A slight shift of the helm and the condition is corrected. Thus, in the thickest of harbor fogs, or in heavy rain or in blinding snow, American ports will present a safe entrance to vessels equipped with "ears," the installation of which costs less than a thousand dollars.

Diagram showing the watch-case receiver. This type of receiver is used exclusively in radio. It is small, light and durable.

the thin sheets of iron, or the diaphragm, is attracted. When the feeble radio-currents arrive at the telephone receiver, all the energy is used in magnifying the attraction that the magnet exerts on the diaphragm. This diaphragm is an exceedingly sensitive piece of telephone mechanism. It takes very little energy to move it. Telephone receivers will not operate when alternating current is used. The current moving in one direction would neutralize the current moving in the opposite direction, and there would be no vibration of the diaphragm. Therefore, the ether waves, or radio waves, which are alternating current must be changed by means of the crystal or vacuum tubes when used as detectors.

Receivers look more or less alike to a beginner; but there is a vast difference between them, especially on the inside. A receiver, to really work right, should be wound with copper wire; but the sole idea, or principle, of the receiver hinges on the fact that there must be many turns of wire very close to the iron core. Receivers are usually rated by their resistance; but this method is entirely wrong. The easiest way to rate receivers is by the resistance of the wire used; but a great mistake is made when this is done, as this resistance is detrimental to the telephones. What is expected from a telephone receiver is the number of turns, or ampere turns, with the least amount of resistance. To get this resistance, a larger size of wire could be used; but when this is done, it will be found that, owing to the thickness of the wire and the distance from the poles, the resistance will increase, thereby lowering the efficiency of the phones.

But this is absolutely contrary to correct receiver design. As the receiver has the resistance, it lacks the number of turns and, actually, less

wire is used. This will give the receiver less efficiency in its work, as the high resistance will deaden the signals. Each receiver will have a total resistance of 1,000 ohms. The two receivers in series will have a combined resistance through which a current of 2,000 ohms must pass. It does not pay to go much higher than the 2200-ohm receiver. It is far better to secure the extra value in getting the very best mechanical design. As the wire used in receivers is very fine, great care must be exercised, when the receiver is open, not to touch and break these fine wires where they connect to the binding posts located inside the receiver.

Another thing in a receiver that may be greatly improved upon is the diaphragm. It is evident that if the diaphragm is to give out sound, it must be able to vibrate freely. Some of the trouble with receiver diaphragms is

How two receivers are connected and how the electro-magnets appear inside the receiver.

due to the fact that they have not sufficient clearance from the pole pieces, making them inoperative. When this is evident, tighten a little on the cap and notice the result. If no change is noticed, then remove the cap, reverse the diaphragm, and then rest the receiver.

If the diaphragm does not clear the pole pieces, a paper washer may be used. The washer is inserted between the base of the receiver and the diaphragm. The iron diaphragm is held in position by means of the cover and the action of the poles. Should a current pass through the coils of the bobbins, the pull of the poles on the diaphragm will be varied. This variation causes the vibration of the diaphragm and, consequently, produces sound. This is satisfactory in most cases.

Plate Voltage an Important Element of V-T Transmitters

By John Kent

ONE of the most essential parts of any radio transmitter is the correct high-plate voltage applied to the plates of the vacuum tube. A very good plan to follow in the construction of any type set, is to design the apparatus so that it will work efficiently with as few pieces of apparatus as possible; and yet, parts may be added from time to time that will improve the set in general and not put on the builder too great a financial stress. A simple vacuum-tube transmitter is no more complicated than the average regenerative receiver, which it resembles. A simple vacuum-tube transmitter making use of the standard parts and utilizing the B batteries for high-plate voltage may be assembled easily in any radio amateur's workshop.

The parts needed for a small transmitter consist of an inductance—which is used as the inductance for the antenna as well as for the grid—plate coupling-coils of a vacuum tube and its controls; a variable condenser; a means of modulating the currents generated by the oscillator of a high voltage

source for the plate circuit and a microphone.

For the plate voltage, ordinary B batteries may be used. However, use batteries that have a variable voltage from 22 to 500 volts. This will enable the operator to cut in just the amount of power needed for the plates of the tubes.

The ordinary flashlight cells will not work so well, because there will be quite a call on the battery and, of course, these batteries will not hold up and will have to be renewed frequently.

If a transmitter tube is used, the plate voltage will have to be between 350 and 500 volts. Hundreds of amateurs who are now using a transmitter for C-W (continuous wave) work, employ the Colpitts circuit in order to know what the plate voltage does. It may be repeated that a good battery for the plate voltage makes the set work in a satisfactory manner. Signals have been transmitted over some distances, and by using the regular transmitting tube the range is increased considerably.

Regarding the aerial, the average

radio fan will have to improve upon his aerial which is being used for broadcast receiving. It is quite impossible to send out signals of a wave length, and keep within the law, on a single wire 100 feet long. The radio fan will have to build an antenna for his sending set which will give him a sending wave-length of 200 meters. Such an aerial may be constructed by building a four-wire inverted-L aerial, 50 feet high and about 100 feet long. Particular care should be taken in the erection of it. It should not be placed near metallic objects, and the best of insulation should be used.

Satisfactory results will be secured only after careful adjustment of the various pieces of apparatus used. Do not be discouraged by the first results, which are often very poor. Further experimenting, the changing of a tube, renewing a battery, lighting the tube more brightly, will increase the radiation, and improve the experiment. A thorough understanding of the apparatus, and the workings of the circuit, and patience, will work wonders.

How to Use Your Bed Spring as an Aerial

(Both photos C. Kadel & Herbert News Service)

ments, there are certain essentials which must be provided: The correct aerial, the proper ground, a means for altering the wave length, an instrument for changing the radio frequency, audio frequency, and the correct telephone receivers. The large half-tone shows Harry Luckert, of New York, who is using his bed spring as an aerial, and a very good aerial this useful domestic element makes. Mr. Luckert was refused permission to erect an aerial on his roof—and utilized his bed. He has accomplished surprising results, hearing WWJ, Detroit; KDKA, Pittsburgh; WGY, Schenectady, and WJZ, Newark. He is using, as may be seen, a one-tube receiver of the regenerative type, consisting of two variometers, and a vario-coupler. This set is carefully shielded and he claims his results are due largely to this, admitting, however, that his location is apparently favorable for long-distance reception. The smaller half-tone shows the rear view of the set with Mr. Luckert's finger pointing to a variometer. This set is small and very compact.

There is nothing complicated about radio reception. The apparatus may be of the simplest sort. If the distance to be spanned is relatively small, but little experience is necessary; for anyone may turn the knobs and adjust the detector. No license is required and anyone may intercept radio waves without formality of any kind. The

cost is low, considering the wonderful possibilities of a receiving set. After all, it is a question of what is expected of the receiving equipment, and successful results demand that the receiving equipment be fitted to the requirements of the owner. No matter how simple a receiving set may be, or how modest the require-

Latest Important Radio News of the Week

IN Missouri a movement was started recently for state control of broadcasting. This movement is showing signs of spreading to other states, and it was the radio interests of Massachusetts that suggested the conference here between the radio and motion picture people. It was believed that the best time to hold the conference was during the Chicago Radio Show, the first manufacturers' show ever held, because the leaders in the industry would be here.

"Listening In," by Carlyle Moore, will be produced out of town October 23, with Ernest Glendinning in the leading role.

Amsterdam, which boasted the first successful Marconi wireless telephone communication with London, is broadcasting concerts regularly from The Hague to London, thus following the example given by America. American enterprise and initiative have supplied the Amsterdam Stock Exchange with direct cable communication to New York.

Dr. Albert Abrams, of San Francisco, originator of the electronic method of diagnosis and treatment of disease, is in New York. He claims that missing persons can be located by radio. Dr. Abrams visits the East, seeking support for clinics for his theory in this country and Europe. In an interview he expressed his eagerness to give all his time and energy to these clinics and to contribute the needed apparatus. The "Electronic Reactions of Abrams" have elicited highest praise from his followers and provoked bitter criticism from doctors of medicine and other scientists. As a retort to criticism in the "Journal of the American Medical Association,"

Dr. Abrams resigned from that association. Dr. Abrams says all material things are radio-active and that sufficiently delicate apparatus can measure the degree of radio-activity and determine a substance being examined without even seeing it. Dr. Abrams says he has devised such a sufficiently delicate apparatus. "A drop of blood," said Dr. Abrams, "with its billions of electrons, is a condensation of the multitudinous vibrations of the body."

With the work of installing a large radio broadcasting station at Police Headquarters, New York, the Western Electric Company has begun putting in receiving sets in police stations, starting first with the borough headquarters station. Material for the Bronx headquarters in the Bathgate Avenue Station has been delivered and installation will start immediately. It has no apparatus for broadcasting and comprises the usual reception apparatus, with amplifiers and loud speaker. All notices sent from the general headquarters will be copied.

E. F. W. Alexanderson, inventor of the Alexanderson alternator, is expected from Sweden next month.

Senator Marconi announces that he will take a personal interest in building up radio interest in his native country, Italy.

European electrical scientists and radio experts of international reputation will visit America and meet this country's radio experts at the National Radio Show, to be held at Madison Square Garden the week of November 29-25.

What a Microphone Looks Like

TWO buttons, or carbon granule chambers, characterize the Western Electric microphone used in WBAY, New York. One button is located on each side of the vibrating diaphragm, so that at any given point in the vibration one button is compressing carbon granules while the other is releasing pressure. This means that current flow, affecting the voice transmission, is being increased on one side of the diaphragm and decreased on the other.

Every fan who has studied the action of the single-button microphone knows that its results are not exactly proportional to the amplitude of the sound waves producing them. Some distortion takes place. With the two-button device this distortion is cut down tremendously. The two buttons of the microphone are connected with one side of the transformer—or in telephone language, the repeating coil—in such a way that the resulting currents are both in the same direction and their combined effect is the production of waves that are quite free from distortion.

The electrical equipment is so arranged that another type of transmitter may be used when desired. It is not a microphone at all, but what is generally known as a condenser transmitter. It contains no little cups of carbon granules which characterize the microphone although it has a vibrating steel diaphragm and makes use of air damping. It requires considerably more preliminary amplification than the microphone but it has certain characteristics which at times makes its use desirable.

He Had Something to Brag About!

Radio Bug:—"Son, I can't brag about your quality or modulation, but you sure are there with the distant audibility."

The Radio Primer

Weekly A B C of Radio for the Beginner, in which Elementary Facts and Principles Are Fully and Tersely Explained

By Lynn Brooks

This larger size of battery, also a B battery, is known as the variable type. This battery can be used where a change of voltage is required.

WHAT is the variable B-battery used for? How can you tell it from any other batteries?

The variable B-battery is used in conjunction with the plate of the tube to carry out the principle of making the tube function. The positive pole of the B-battery is connected always to the plate of the vacuum tube whether the tube is a detector or an amplifier. If, by accident, the negative connection from the B-battery is connected to the plate the tube will not function at all. The B-battery is a necessary element for the tubes and may be detected easily by their size. The accompanying illustration shows what the variable B-battery looks like. It is much smaller than the storage battery. The variable taps are brought out on the top of the battery.

Are there any non-variable B-batteries?

Yes—B-batteries of the non-variable type. They are the same size, carry no taps, have a constant voltage and can be used with fixed voltage.

Describe the storage battery.

A storage battery consists of a number of cells, each cell made up of a number of plates and grids in an electrolyte solution of such character that the electrical energy supplied to it is converted into electrical energy—a process called discharging.

What is the theory of the storage battery?

The action of the storage battery is practically the same as that of the primary battery and is subject to the same general laws. The cells of a storage battery are connected in the same way as primary cells and, when charged, are capable of generating a current of electricity in a manner similar to that of the primary battery. It differs, however, from the primary

battery. It is capable of being recharged after exhaustion by passing an electric current through it in a direction opposite to that of the current of discharge. This difference constitutes the principal advantage of the storage battery over the primary battery.

* * *

How is the electrolyte generally used?

The electrolyte consists of a weak solution of sulphuric acid which permits ready conduction of the current from the primary battery. The greater proportion of acid, within certain limits, the smaller the resistance offered.

* * *

What is the effect of the current passing through the electrolyte?

It decomposes the water into oxygen and hydrogen. This is indicated by the formation of bubbles on the exposed surfaces of both plates. These bubbles are formed by oxygen gas on the plate connected to the positive pole of the primary battery, and hydrogen on the plate connected to the negative pole.

* * *

How is the electrolyte prepared?

One part of chemically pure concentrated sulphuric-acid is mixed with several parts of water. The proportion of water differs with several types of cell from 3 to 8 parts, as specified in the directions accompanying the cells.

* * *

In preparing the electrolyte, how should the water and acid be mixed?

The mixture should be made by pouring the acid slowly into the water. Never do it the reverse way as an accident will result. It cannot be too strongly stated, in mixing the liquid,

B battery of the non-variable type.

that it should be stirred with a clean wooden stick, the acid being added slowly to the water. The acid is corrosive and will burn the flesh. Distilled water should be used in preparing the solution. The mixing of the two ingredients causes them to become very hot.

* * *

How should the cells be filled?

Sufficient of the electrolyte should be poured into the jars to either completely cover the plates or to come within half an inch of the top of the jar. Large cells should be filled by means of an acid-proof pump. During this operation wear rubber gloves.

* * *

What about the density of the electrolyte?

It should never exceed 1,300 when the battery is fully charged.

* * *

What should be done with the old electrolyte?

When a battery is taken down, the electrolyte may be saved and used when reassembling the battery, provided great care is exercised when pouring it out of the jar not to draw off any of the sediment. It should be stored in convenient receptacles, preferably carboys which have been thoroughly washed and never used for any other purposes.

* * *

What is the voltage of a secondary cell?

This depends generally on the density of the electrolyte, the character of the electrodes, and the condition of the cell. It is independent of the size of the cell.

* * *

What are the colors of the plates?

In the case of formed plates, and before the first charging, the plates that are positive are of a dark-brown color with light- or red-gray spots, while the negatives are of a yellowish gray. These spots, on the positive plates, are small particles of lead sulphate which have not been reduced to lead peroxide during the process of forming. They represent imperfect sulphation.

THOUSANDS of radio beginners have come into the radio field since summer. They will find "The Radio Primer," published weekly in RADIO WORLD, a regular source of instruction and aid. For this reason, RADIO WORLD will republish, from time to time, some of the valuable primer articles that appeared in its early issues. These articles, by experts, contain a vast amount of radio information that cannot be duplicated. Every beginner will find them necessary to the building of sets and cooperative with the new material being printed weekly.

Regenerative V-T Receiver for Short Waves

Describing Photographs on Front Cover of This Issue

By Fred. Chas. Ehlert

A MATEURS are asking constantly: "What is the most efficient hook-up, or diagram, whereby loud signals may be obtained?" The tube detector undoubtedly is the most sensitive detector yet devised; but a new circuit has been created, to be used with the vacuum tube, which will render the tube self-amplifying. This is the regenerative circuit.

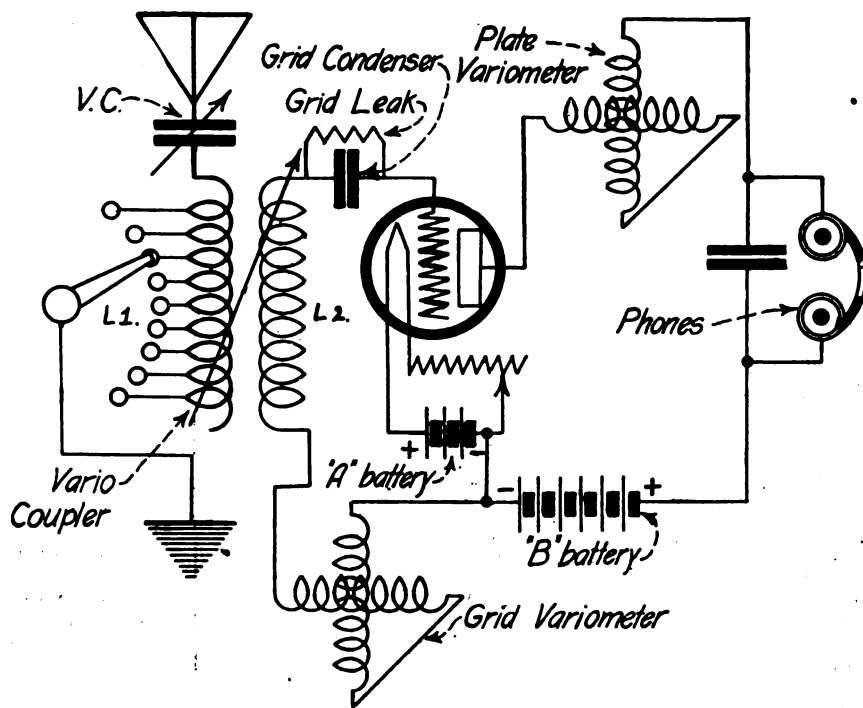

A vacuum tube, when hooked-up to a special circuit, will generate oscillations whose frequency can be controlled by varying the capacity and inductance of the circuit. The inventor of this circuit is Major Edwin H. Armstrong, U. S. A. He has contributed what is universally acclaimed as the most important invention since radio was first discovered. One type of a circuit where regeneration can be produced is shown in the accompanying circuit, whereby variometers are employed to produce that effect. All regenerative circuits are delicate to operate for the regenerative effect which gives rise to all kinds of noises in the telephone receivers.

The equipment needed for this circuit are two variometers, one variocoupler, grid condenser and leak, tube socket, and tube detector, with batteries and phones.

This circuit is a short-wave regenerative circuit employing the variometer in the plate circuit for production of such regeneration as that of Major Armstrong's invention. L-1 is the primary winding of the variocoupler and L-2 the secondary of the variocoupler. In series with the primary is a variable condenser, but this is to be "tried out" to see if it is needed. Personally, I believe it should be left out.

A grid condenser and leak is shown which should be connected in series with the grid of the tube. This grid condenser has a capacity of .00025 mfd., and may be purchased at most any radio shop.

The 22-volt battery is connected in the plate circuit of the tube with the plus side of the battery connected to the plate of the tube. One side of the filament of the tube is connected to the wire running from the telephones to the grid variometer. Be sure that the 6-volt battery is connected in right. Before making connections, be positive that the battery leads are correct. If the leads from the 22-volt B-battery become crossed with the filament of the tube, don't be surprised if your

Schematic diagram of a complete regenerative receiver employing variometers. One variometer is placed in the grid circuit while the other variometer is placed in the plate circuit of the vacuum tube. This receiver will respond to the shorter waves with a good volume of sound. Suggested by Fred. Chas. Ehlert. Drawn by S. Newman.

tube does not light. This means that you have a burnt-out tube and that another tube must be purchased. But be sure that all connections are right before lighting.

The rheostat in series with the tube which controls the filament lighting of the tube is also shown. In case it is turned too high, the tube also will burn out. These precautions will have to be taken care of, but aside from this, there is not much to worry about. Generally the socket for the tube is marked as follows: P, for plate; G, for grid; F plus and F minus for filament. These two F marks are to be

connected to the 6-volt storage battery. Be sure to connect them to the proper polarity with the rheostat. In working this set, you will learn by experience when lighting the tube that it will start to hiss. The most sensitive spot is just below where the tube starts to hiss.

Again I caution you not to turn the filaments too high, as probably they will burn out the tube. By keeping the filaments at their proper brilliancy the tube's life will be lengthened. By using the tube you will soon learn its great advantages over the crystal detector.

WJZ Celebrates First Anniversary

WJZ, radio call-letters on the lips of thousands of radio enthusiasts, held its first anniversary services during the evening of October 5, when several of the artists who broadcast from WJZ last fall again visited this station.

It is generally regarded that KDKA is the father of broadcasting; also that WJZ popularized the broadcasting idea and introduced it in the Metropolitan area, where it attracted the best of talent and, with the assistance of New York radio publications, aroused the nation to the great possibilities of radio broadcasting.

WJZ was officially opened October 5, 1921, at 1:55 p. m., when several records were played to enable the radio audience to tune in their radio sets to receive, a

few minutes later, the play by play results of the World Series.

The response to the broadcasting by WJZ was immediate, as suggested by letters received from Massachusetts, West Virginia, Ontario, Pennsylvania, New York, and New Jersey.

The first artists to broadcast in person were: The Shannon Four, well known recording quartette, consisting of Charles Hart, tenor; Elliott Shaw, baritone; Wilfred Glenn, bass, and Louis James, tenor. Soon thereafter the foremost recording team, Billy Jones, tenor, and Ernest Hare, bass-baritone, entertained the growing invisible audience. Two prominent instrumentalists, Constance Karla, violinist, and Anna Welch, harpist, followed and other artists of note.

Radiograms

Latest Important News of Radio Garnered from the World Over, and Reduced to Short Wave-Lengths for the Busy Reader.

(C. Central News Photo Service.)

Sir Thomas Lipton as he appeared just after talking, by radio, across the Atlantic. The instrument at his left is the transmitter, or acousticon, into which he spoke, and which started his words on their long journey to London. Commenting on the experiment, Sir Thomas said: "This is the biggest thing of its kind in the world—and worthy of America as a big part of this world."

AT WOR, the broadcasting station of L. Bamberger & Sons, Newark, New Jersey, an attempt was made, last Saturday night, to bridge the Atlantic Ocean with the human voice. W. S. Moler, publicity manager for WOR, reported that a message had been received from Gordon Selfridge, "the Marshall Field of London," stating that the voice was heard "more or less distinctly." The person who spoke into the transmitter at WOR was Sir Thomas Lipton, at present visiting the United States. Mr. Selfridge's cable also stated that a vocal selection was distinctly heard. According to Mr. Moler, this is the first time the human voice has been broadcast such a distance, over a 400-meter apparatus. It was necessary to tune up to over 2,000 watts, or twice the ordinary capacity of a 400-meter outfit. Sir Thomas and a few friends went to Newark to make the experiment. The radio message was sent to Mr. Selfridge at Marconi House, London.

Consul Wesley Frost, Marseilles, states that owing to governmental restrictions the development of amateur radio clubs in France has been so retarded that up to date there have been few in existence outside of Paris. The Radio Club of France has recently established its first branch office at Marseilles, and its local representative has offices at 44 Rue des Abeilles and in the grounds of the French National Colonial Exposition.

Sweden sent missions to England, France, Germany and the United States, two years ago, to study the various wireless systems and types of apparatus in use. In 1921, the mission,

under the direction of Seth Sjungquist, head of the Royal Telegraph Administration of the Kingdom of Sweden, visited America to inspect the high-power station of the Radio Corporation and to particularly see the Alexanderson alternators in operation. When the Reichstag met this year it sent a special legislative committee to England to study the vacuum tube as developed there, and it was only after hearing this report that the Reichstag recommended the use of the Alexanderson alternator and authorized the signing of the contract by the Telegraph Administration.

The installation of small radio outfits in all lighthouses of the Department of Communications, Mexico, is to be given a trial. Two sets are being supplied, after which, if the results are satisfactory, all lighthouses will be similarly equipped.

The announcement, "Flowers sent by radio," is made by a Bond street, London, firm of florists. "Altogether we have 2,300 agents," said the manager of the firm, "and flowers can be delivered in all parts of America and Canada in a few hours. The idea is spreading rapidly in England, though we receive more orders from the other side than we send."

The latest use of radio is to locate missing relatives. Amateurs are requested to send out general or QST calls containing complete descriptions of the person missing with such other data as may be given them for broadcasting.

An interesting innovation in broadcasting was started last week at station WLW, Cincinnati, when Paul Briol inaugurated a tri-weekly book review by radio. Books by the best authors of the present were reviewed briefly and interesting anecdotes regarding the authors were read. This feature will be worked into the evening programmes on Tuesday, Thursday, and Friday nights.

For the third time, American radio amateurs plan communication with continental stations using their own amateur sets. This year's transatlantic tests will be conducted from December 12 to December 31 by the American Radio Relay League in cooperation with the amateur organizations in Canada, England, France and Holland.

English manufacturers have organized for the purpose of building and operating broadcasting stations with the approval of the government. Special wave-lengths will be allotted and stations will be erected in various areas, so that the whole territory of England will be well covered, and yet no interference will be experienced. By following a systematic method of locating stations and distributing wave lengths, the English will not have to suffer the early inconveniences which accompanied the advent of broadcasting in this country.

Secretary of Labor Davis started broadcasting, on October 2, for the Department of Labor through the Naval Air Station at Anacosta, NOE. The service will be for three fifteen-minute periods each week from 7:15 to 7:30 every Monday, Tuesday and Thursday. Secretary Davis, in his first broadcast, presented a short exposition of what the Department of Labor can do and is doing for American wage earners. A definite program will be announced later.

Sunday religious services have been added to the weekly schedule of WGY, Schenectady, New York. Every Sunday, a Schenectady church will be connected to the radio transmitting-outfit by land wire and the entire service of that church will be sent out, beginning at 10:30 a. m. At 4:30 o'clock, every Sunday afternoon, vesper services will be held in the studio of WGY, and a short address will be delivered.

W. K. Vanderbilt has departed from Southampton, England, on his new motor-yacht, said to be the most costly and luxurious pleasure craft afloat. Her radio apparatus, it is reported, is as powerful as that of any of the transatlantic liners.

The first radiophone exchange in the world, installed by the Air Ministry, is in daily use at the London Air Station, Croydon, England. Its main purpose is to connect the aerial-traffic controller with the pilots of airplanes operating between Great Britain and the Continent.

Radio and the Woman

By
Crystal D. Tector

I AM not unmindful of the fact that radio has me on my toes most of my waking hours—and, perhaps, more of the hours when I should be asleep than my doctor would approve—but even after a night with the “owls” I feel as chipper and gay as if I had set up counting an unexpected legacy. Most everything can be overdone. A plethora of riches produces nausea. One can have too much of a good thing, and all that; but I have yet to become bored by the varied excitement that radio throws in my way.

* * *

The other night, for instance, I attended a radio party down on Long Island. The hostess was one of the most charming young matrons of New York's very charming set. She sent out cards for a hundred guests. “You are invited to a radio evening,” was the simple but alluring phrase in the corner of the invitations. Of course, I had the usual argument getting Friend Husband to put on his evening togs. He swore the weather was still too warm and made other petty excuses, but I had my way. Luckily some dear friends motored us down.

* * *

Our hostess has one of those huge country homes that make one positively jealous. Her big living room,—I suppose I should be “class” and call it a “reception room”—where the chairs were arranged in a semi-circle before a radio-set banked with flowers. All one could see were the tuning knobs and the huge loud-speaker jutting forth from a mass of pink roses. When the music and the vocal selections began to come through, the scene was unusually attractive. I believe that it was the first affair of its kind ever held in America. If there have been others I have never heard of them—and if any of my readers can enlighten me, I wish they would write.

The programs rendered that evening were particularly fine. Only one number—a violin solo—seemed to suffer until a few turns of the dial and when the minimum of volume was reached, everything was perfect. Believe me, there was not a bored person in the room. Every one remained seated until the time tick came through from Washington, and all considered it quite a novel thing to see if their timepieces were correct.

* * *

The broadcasting programs over, a supper was served. While this was the “matter of the moment,” the chairs in the reception room were removed and the floor made ready for dancing. And—after some maneuvering, during which dozens of men, who never before had taken even the smallest interest in radio, peered into the set and asked a thousand questions—we picked up dancing music being broadcast from St. Louis! Imagine the charm of it! Dancing on Long Island to music being played in St. Louis.

I wish I had the space to give more than this mere outline of this very attractive affair. But I can drop a hint to all hostesses who are looking for something new this winter in the way of entertainment: Give a radio party. If you want some inside suggestions, drop me a line and I will help you all I can.

* * *

I have had a rather big “mail” since my last “copy” was written for RADIO WORLD. One of my correspondents who requests me to withhold both her name and her address, because her husband would “never forgive her” if he knew that she wrote to me, wants to know if iron pipe may be used for stays on an aerial 40 feet high, or is iron pipe obstructive to radio waves. Listen, dearie—and don't tell your husband—but iron pipe may be used for poles to support your aerial, but it will absorb some of the radio waves. Wood is better.

Heard Atlanta, Georgia, in Des Moines, Iowa

EDITOR, RADIO WORLD: In RADIO WORLD of September 23, page 29, “Who Is This Broadcaster?” I heard this program very plainly, and as I have been keeping a radio log I find that “Little Red Riding Hood” was given by a woman, in a child's dialect, from the broadcast station WSB, the “Atlanta Journal,” Atlanta, Georgia. I heard this program which started at 10:45 P. M., and ended in the morning; for when he signed off the operator said, “Good morning.”

As a rule, WSB is very clear here and everybody here looks to 10:45 as they know Atlanta, Georgia, will come in no matter how bad the weather is—static or not. This program was received on one-step single circuit using an A-P detector and one 301-Cunningham, amplified bulb. The outfit is home-made.

Hoping this information will help out radio fans.—Jack Clemons, Des Moines, Iowa.

* * *

Also in Cleveland

EDITOR, RADIO WORLD: On August 16, 1922, at 1 A. M., we received the message, and commented on the hour for a bed-time story and we heard the entire program. It was from Station WSB, Atlanta, Georgia.—Mrs. W. C. Blackburn, Cleveland, Ohio.

Only Relative Values

Always remember that the divisions and markings on dials and switches have only relative values, and do not directly indicate wave-length. They afford an easy means of resetting your instruments to tune in to a certain station.

New York Hotel Phone Operator Now Answers by Radio

Here is Miss Millie Culligan, telephone operator of the Vanderbilt Hotel, New York City, who was not content to remain the operator of an ordinary switchboard, but so familiarized herself with the radio system installed in the Vanderbilt that she is able to operate a set to perfection. Radio is fast becoming an essential of the leading hotels and hotel systems of the East. In general, it is now used for paging guests. During the past week, when New York City was crowded with guests—owing to the World's Series and Banker's Convention—a number of hotels installed temporary radio sets to keep their guests in touch with the latest news.

Interesting News Photos Collected for Busy

(C. Central News Photo Service)

Did you hear the news of the World's Series Baseball played at the Polo grounds, New York? Here is the room from which it was broadcast, play by play. J. C. Smith is the operator who is "shooting" the news to the millions who could not get seats for the big event.

(C. Central News Photo Service)

The world's greatest radio station is opened, and here is a bustling commercial institution, and so it is, for it is the greatest America Station, situated at Rocky Point, near Port Jefferson, of all the world. From it, President Harding flashed radiograms part of the receiving room into which messages are delivered for recording code messages. Radio Central, as the big station is of separate transmitters so as to ensure simultaneous communication at the Rocky Point Station enable the powerful transmitters to modulate, or control, the flow of power from the alternators employed at Radio Central. It consists of a line of 410-

Clara Kimball Young, famous motion-picture star, talking over the transmitting apparatus of "The Examiner," Los Angeles. On this occasion Miss Young recited the late James Whitcomb Riley's poem, "That Old Sweetheart of Mine," and she received letters from radio fans even in the Middle West who heard her. The apparatus at her right is a 250-watt radiophone.

Graphs of the Week Radio Readers

Some reproduction of its busy office. It looks like the office of a real operating room in New York City of the Radio Corporation of New York. This station established America as the radio center for the world, greeting to twenty-eight other countries. The half-tone shows a transmission abroad. The typewriters with reels of paper are for use in, in reality, several stations in one. It comprises a number of stations with a number of stations abroad. The magnetic amplifiers operated at long distance. These ferromagnetic devices accurately radiating system, or aerial wires. The latest form of aerial is the towers, or masts, with 150-foot spreaders at the top of each.

(C. Central News Photo Service)

Over in Ridgely Park, New Jersey, they call this "The Dugout." It is a "quick-lunch" establishment, and the enterprising proprietor has installed radio for the benefit of his chef and customers.

The Grand Army veteran in the half-tone at the left wanted to listen in and the owner of a set obliged him. Before he had satisfied his longing, the old soldier was able to tune in himself. He asked, however, that his name should not be published—a request always adhered to by responsible editors. But the old fighter said that becoming acquainted with this new wonder gave him a new lease on life.

In the half-tone at the right, two electrical engineers of the College of the City of New York are testing aerials, one of the most fascinating "test ups" in radio. With the equipment laid out before them, it is possible to tell how aerials will work before being put up, thus precluding the possibility of erecting them in unsuitable locations. The young engineer with pencil and pad is Abraham Ringel. The other is Samuel Miller. RADIO WORLD has frequently referred to the splendid work in radio by the students and the faculty of this New York City institution.

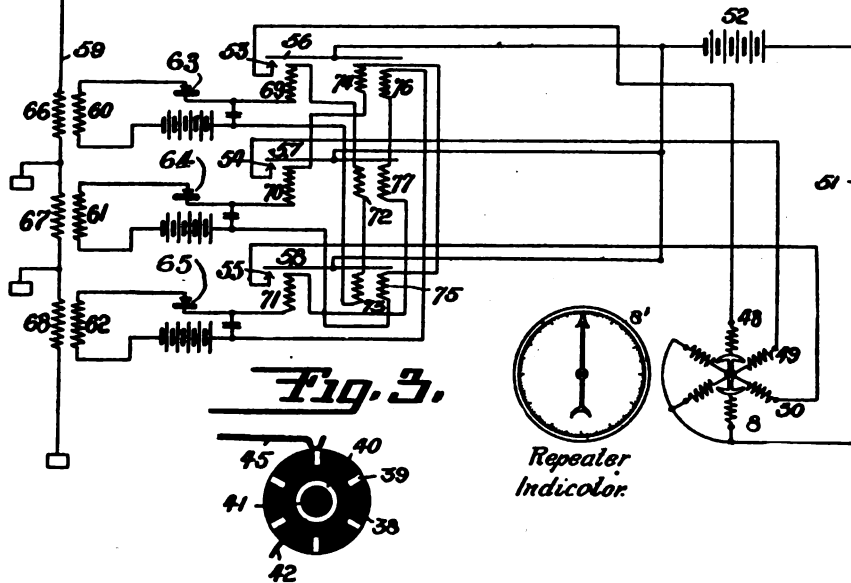

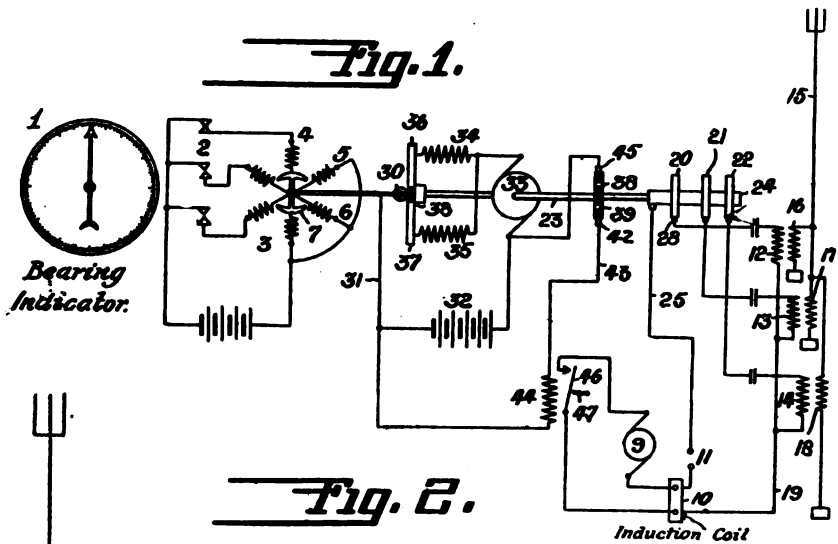

(C. Kadel & Herbert News Service)

Radio Patents

ized by the indirect use of the heating battery, or of some other source; but in either case associating this source with the output circuit battery.

It is well known that the current flowing through the output circuit undergoes fluctuations owing to sudden or gradual internal changes within the power battery. Such fluctuations in the space current of the vacuum tube are very troublesome. The method by which this invention overcomes this error may be explained as follows: Assume that the vacuum-tube circuits are so arranged, as hereinafter described, that the current for the input circuit comes from a source in series with the source for the output circuit. For illustration, suppose there is a decrease in the potential from the output circuit battery due to some internal change; this will necessarily tend

Schematic diagrams of Mr. Sperry's invention, the chief purpose of which is to provide simple and efficient means for causing an indicator, by means of radiant impulses, to follow automatically the movements of another indicator at a distant point.

Wireless Repeater System

No. 1,428,567. Patented, September 5, 1922. Patentes: Elmer A. Sperry, Brooklyn, N. Y.

THIS invention is for the purpose of automatically transmitting the readings of an indicating member by wireless to a distant point. It is particularly useful, the inventor claims, in automatically transmitting by wireless to an aircraft or other distant point the readings of a compass, fire-control instrument, or other indicator on a ship, whereby the ship's heading, or the bearing of a target observed from the ship may be constantly

communicated in safety to a distant point.

Such a system has especial uses in the aerial ordnance-control for heavy guns where the target is only visible from airplanes, which signal to the ship or other firing station the bearings of the target. In such a system, it is very desirable that the airplane pilot should know the bearing of his object.

The chief purpose of Mr. Sperry's invention is to provide simple and efficient means for causing an indicator, by means of radiant impulses, to follow automatically the movements of another indicator at a distant point.

Circuits for Electron-Discharge Devices

No. 1,428,754. Patented, August 22, 1922. Patentes: Robert C. Mathes, New York City.

THE sources of direct current potential for the input circuit of an electron-discharge device of the audion type, is the basic element of this invention of Mr. Mathes. It is intended to provide

a more convenient and desirable method than has heretofore been used for securing a desired difference of potential between the filament and the grid of a tube of the audion type. A further object is to furnish a method and means for compensating for fluctuations in the potential of the output circuit battery of the vacuum tube.

Specifically, these objects may be real-

Schematic diagrams of the invention of Mr. Robert C. Mathes for the discharge of electrons.

to decrease the space current between the filament and anode of the vacuum tube. If the input and output batteries are of similar nature, this change, in all probability, will also decrease the potential of the input-circuit battery, which is in series with it, so that the grid potential will become less negative thereby tending to increase the space current to its former value. The compensation would take place in a similar manner for an increase in the voltage of the batteries, due, for instance, to the batteries being charged by some suitable means.

This scheme works especially well if the negative grid-voltage is derived from the drop of potential across the terminals of a resistance which derives its current from a battery associated with the output circuit battery.

You Will Need RADIO WORLD as a Radio Reference

Be sure to see that your file of RADIO WORLD is complete. There will soon be so great a demand for back numbers that the supply will not be sufficient to cover it. RADIO WORLD has been issued every week from April 1 to date. Start with No. 1.—RADIO WORLD. Mail, postpaid, for 15c a copy; any seven copies for \$1.00. Or send \$6.00 for one year (52 issues) and have your subscription start with No. 1.—RADIO WORLD, 1493 Broadway, New York City.

Coming Events

The editors of RADIO WORLD will gladly publish news items of all contemplated radio shows and expositions. Keep us posted by mailing full information.

CHICAGO RADIO SHOW, Coliseum, Chicago, Ill., October 4 to 22. U. J. Hermann, managing director, 549 McCormick Building.

SECOND NATIONAL RADIO EXPOSITION, direction International Trade Exposition Co., Chicago, January 13 to 20, inclusive, 1923, George A. King, director of publicity, 417 South Dearborn Street, Chicago, Ill.

PERMANENT RADIO FAIR FOR BUYERS, Hotel Imperial, New York City. Open from September, 1922, to May, 1923.

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, December 21 to 31,

inclusive. Direction American Radio Exposition Company, 120 Broadway.

TRI-STATE TOBACCO GROWERS' RADIO SHOW, Covington, Ohio, October 21 to 28, inclusive.

NEW YORK ELECTRICAL AND INDUSTRIAL EXPOSITION, Grand Central Palace, New York City, October 7 to 14, inclusive.

SPRINGFIELD RADIO EXPOSITION, Springfield Auditorium, Springfield, Mass., October 3 to 7, inclusive.

SOUTHERN CALIFORNIA RADIO SHOW. Combined exhibition of the Southern California Broadcasting Association, the Southern California Radio Association, and the Southern California Radio Trade Association. Los Angeles, October 9 to 14 inclusive.

INTERNATIONAL RADIO SHOW, Madison Square Garden, New York City, November 20 to 28, inclusive. E. C. Buchignani, director of publicity.

A Warning to Radio-Show Exhibitors

AS to the value of radio exhibitions: Radio expositions are all right in their way. They have a legitimate place in radio affairs—**BUT THEY MAY BECOME A NUISANCE AND A MENACE UNLESS THE INTERESTS OF THE TRADE ARE PROPERLY SAFEGUARDED.**

Radio exhibitions, organized and conducted with an honest regard for radio art, science, and business, are excellent things. When run on go-as-you-please principles by promoters who have nothing in mind except the sale of space to exhibitors, they are likely to do much more harm than good.

For instance, how many of us have visited radio expositions and been confounded by the din and noise, by the barrage of unrestricted announcements and the cannoading by batteries that filled the air with meaningless sounds, making the would-be enthusiasts wonder what it all was about, and sending them out into the night filled with the idea that radio is a noisy, senseless thing.

A properly regulated method of receiving and sending messages in connection with radio shows and in making

business and official announcements, would greatly lessen the resentment of the judicious, and this could, and undoubtedly would, be regulated if practical radiomen had anything to do with the actual management of the show.

Therefore, **RADIO WORLD ISSUES THIS WARNING TO MANUFACTURERS** of radio goods and to all others interested as radio exhibitors:

Don't sign up for space at the next radio show whose representative calls on you for a reservation of space unless that representative can prove positively and convincingly that the board of management contains the names of practical radio men. Even then be sure that these radio men will have something to say about the **ACTUAL RUNNING OF THE SHOW IN ALL ITS PHASES.**

Beware of the radio show promoter who hasn't any more interest in radio than he has in canned milk or typewriters.

RADIO SHOWS SHOULD BE RUN BY RADIO MEN. Until they are, the radio industry and our constantly growing army of "fans" will not get a square deal.—**THE EDITOR.**

General radio-trade problems will also be taken up at conferences of manufacturers. One of these problems will be broadcasting. Many manufacturers believe that the industry is being held back by poor broadcasting, poor programs, and a general lack of knowledge of what the public wants.

Another problem to be discussed is, what is regarded as some, a boycott in England against radio apparatus made in the United States. James F. Kerr, business manager of the Chicago Radio Show, who recently returned from a trip to New York, Boston, and other Eastern cities, reports that not less than 127,000 radio sets, manufactured in the United States and shipped to England, are now being returned to the manufacturers. The Eastern manufacturers were depending largely on their export trade. The Western manufacturers have been better off because the farmers of the Middle West are going in stronger than ever for radio and are making the market one of the busiest ever known.

Chicago Radio Show

THE Chicago Radio Show, the first show ever endorsed by the National Radio Chamber of Commerce and the Radio Division of the National Electrical Manufacturers, promises to be one of the largest trade expositions ever held. When the doors of the Coliseum are thrown open to the public on Saturday, October 14, practically every large manufacturer of radio apparatus will be represented in the show, which will continue until Saturday, October 21. It will be open to the public both afternoon and evening for the eight days.

It will be the first time that the manufacturer has taken the opportunity to meet the jobber, dealer, and public at the same time.

Ed Wynn, the famous comedian, and his company, will put on "The Perfect Fool" the opening night for broadcasting. There will be a society night, a radio ball, a children's afternoon and other features during the week. While the entire Coliseum will be given over to the exhibits, the Coliseum Annex will be given over to meetings.

Radio brings it MAGNAVOX Radio tells it

Make your receiving set complete. Equip it with the wonderful Magnavox Radio that tells it clearly and in full volume to all within reach of its voice

AFTER once using a Magnavox Radio, the Reproducer Supreme, you would no more go back to the telephone headset than you would exchange your electric light for a tallow candle.

With the Magnavox Radio, due to the electrodynamic principle involved in its construction, you hear every program or message at its best.

A Magnavox Radio so increases the use and enjoyment of any receiving set that it is considered the one essential part of the receiving station.

R-3 Magnavox Radio with 14-inch horn (here illustrated), is ideal for use in homes, offices, etc.

Price \$45.00

R-2 Magnavox Radio with 18-inch horn for those who wish the utmost in amplifying power; for large audiences, dance halls, etc.

Price \$85.00

Player board

OUTS

1	2	3
---	---	---

Teams

1	2	3	4	5	6	7	8	9	10	11	R.	H.	E.

BALLS	1	2	3	4	STRIKES	1	2	3
-------	---	---	---	---	---------	---	---	---

To operate this radio playerboard, cut out the small squares and the baseballs on either side of the diamond. Paste these onto cardboard if possible. Then write in the names of players and their position. Five extra squares may be used for either team when pinch hitters or substitutes are put in the lineup. The operation will then be much the same as on the electric player boards used in halls to report ball games.

Place the square containing the name of the first man at bat on home. If he singles, move him to first and place the second batter on home. If one strike is called, place one of the baseballs over the square marked No. 1 under STRIKES. If the next delivery is a ball, place another of the baseballs over the square marked No. 1 under BALLS. Advance these base-balls as the balls and strikes are called. When one is out, place one of the baseballs over the square marked No. 1 under OUTS. A small dot may be placed in the square marked HITS and ERRORS as these occur and at the close of the half of each inning score the runs made in the SCORE BY INNINGS space.

Take the principal players of the Giants and Yankees, or make up your own teams, and following the games as they were played at the Polo Grounds, or any other games, you can have baseball at home all winter.

From Pole to Pole

THE modern school-boy knows radio from A to Z, and can rattle off the terms with a fluency that staggers the casual dabbler in the new art. In some sections of the country, however, only rumors of wonders of radio have seeped in and the native isn't always quite sure what it is all about. In Bleeker, a little hamlet near Gloversville, New York, a progressive farmer was erecting poles for his aerial for the purpose of getting crop reports and weather forecasts from WGY, the General Electric Company's broadcasting station at Schenectady, New York. A neighbor happened along and learning that the work had something to do with radio asked: "Which pole does that feller sing off of?"

Tower Mfg. Company
 113 STATION ST BROOKLINE, MASS.

**Complete Radio Station
 for Rent**

THE Navy Department is offering its radio station at Miami Beach, Florida, for lease to the highest bidder, pending the enactment of legislation authorizing its sale. Bids will be opened at the Central Sales Office, Navy Yard, Washington, October 17, 1922. NGE, the station, is completely equipped and, on 1620 meters, has a radius of about 300 miles.

The site comprises 13,650 square feet on Miami Beach, and includes an operating building, bungalow, storehouse, steel antenna-towers and complete radio-equipment. The operating building is built of terra cotta faced with stucco, contains machinery, operating, store and wash rooms, and an office built in 1921. The operating room is modern, being sound proof and copper-screened on all sides. The bungalow contains six living and sleeping rooms, suitable as quarters and fully equipped for the radiomen of the station.

Two steel towers, 210 feet high, support the large L-type and shorter T-type aeri-als, both of which are said to be in good condition.

The equipment includes a rotary spark-gap transmitter, generators, motor generators, switchboards, transformers, protective devices, condensers, loading coils, instruments, tools, and batteries; even clocks and typewriters.

Bidders, who are required to be of the Caucasian race, must make an offer of a yearly rental, not to exceed five years, and forward three months' rental in advance. The successful bidder must furnish a \$25,000 bond to the Navy.

Radio Goods that Stand the Test

Manufacturers, send a sample of your goods to our Technical Editor, Fred. Charles Ehlert, 6908 Pleasant Street., Queens, Long Island, N. Y. It will be carefully tested and returned. If your goods satisfy our experts, RADIO WORLD'S endorsement will be published in our merchandise department without charge or obligation of any kind on your part. This is a free service on the part of RADIO WORLD, calling for no expense whatsoever on the part of the manufacturer, except the sending of a sample of his goods.

Excellent Vernier Variable Condenser

(Manufactured by Frank P. Marsh, 50 Linden Street New Haven, Connecticut)

A WELL-CONSTRUCTED variable condenser of the vernier type. It has 23 plates with three end-plates to make up the vernier condenser. Its capacity was found to be .00058 mfd., employing the 23 plates, while with the vernier alone the capacity was approximately .00007 mfd. The construction of the condenser is as follows: End plates are of bakelite, with edges and faces polished. All plates are of the best grade even-gauge hard aluminum with edges cut to allow no burrs. The movable plates are mounted on a solid brass shaft accurately spaced and locked to correct position. The vernier which is a handy element of this condenser is made up of three plates with the center plate movable. It is a two-knob control, one knob controlling the condenser adjustment while the other knob, located in the center of the condenser knob, is used for the vernier adjustment. This enables the operator to adjust his set for fine tuning of concerts and gives loud signals. The condenser is nicely finished and when used in a set comprises a satisfactory condenser ready for panel mounting.

Vermica Variable Condenser

(Manufactured by C. S. Cherpeck, 3125 Davlin Court, Chicago)

A GOOD and inexpensive variable condenser is now being placed on the market. By means of a special screw-adjustment, fine, accurate tuning is made possible. In fact, with only a single knob, or dial, what is essentially vernier control is obtained.

Another feature of this condenser is that it can be knocked about without being put out of order or having its efficiency impaired. This makes it a handy and ideal piece of equipment for experimental, amateur and general radio work. Its capacity was found to be .0005 mfd.

Its convenient size makes it readily adaptable for either table or panel mounting. It can be mounted on any size panel up to half an inch. The Vermica Variable Condenser is neat and attractive.

Correction

In RADIO WORLD, Vol. II., No. 1, dated September 30, in the published test of the "P-T" Ultra-Sensitive Crystal Detector Contact Wire, the address of the manufacturer was incorrectly given. Address: "P-T" Crystal Contact Co., Box 1641, Boston, Mass.

Radio Goods Active As Indoor Season Begins

RADIO goods have seen enough activity lately to confirm the views of leaders in the business that the slump which occurred early in the summer was merely seasonal and that the business would return to its former scale in the fall, says C. F. Hughes, financial authority on the staff of "The World," New York. In other words, it appears certain now that radio is essentially a feature of indoor entertainment. A good deal of progress has been made in perfecting merchandise plans and in standardizing equipment. Retail stores are now offered the buying discount they were after and also may guarantee the various sets, which was another of their desires.

Radio Now One of the Greatest Assets of Shipping

By W. Randall

SIR THOMAS FISHER, C. B. E., R. N. (retired), general manager of Canadian Pacific Steamships, Ltd., London, who is now in America, says radio is one of the greatest assets of maritime service.

"The most enthusiastic supporters of Marconi did not dream that radio telegraphy would develop to the extent it has during the past twenty years," said Sir Thomas to a representative of RADIO WORLD. "The usefulness and value of the new system of communication were soon apparent and radio was at once applied by the British Admiralty at Lloyds. The advancement of the science, insofar as it has affected shipping, has been great, and today no vessel of size is without wireless equipment. The question of safety at sea is undoubtedly the paramount benefit conferred by radio telegraphy; but other considerations, such as the facilities given for commercial and personal communications, and the means provided for keeping passengers informed of world events, are of such vast importance that the conditions of ocean travel have been revolutionized.

"The highest standard of efficiency has always been maintained in the equipment of the ships of the Canadian Pacific fleets. Up-to-date improved radio installation is carried on all ships. The installation in a typical radio room, on the "Empress of Scotland," comprises a one and one-half-kilowatt quenched-gap transmitter, five hundred cycle, with normal daylight working range of 500 miles; one quenched-gap emergency transmitter with range greater than 100 miles; a one and one-half-kilowatt continuous-wave valve-transmitter which has worked a distance of three thousand miles under favorable conditions; type ninety-one four-electrode valve receiver; type one and twenty-seven piano tuner, and type one hundred and twenty-three hydrodyne receiver, capable of receiving signals of a wave length up to thirty thousand meters. Also a direction finding apparatus.

"The Marconi operators aboard our ships tell many yarns about the efforts made by passengers to send the utmost in messages crowded into the fewest words. What is becoming a popular message is "Third epistle, St. John, verses thirteen fourteen," which, upon being decoded, if such a term may be used refers to the text: "I have many things to write but I will not with pen and ink write unto thee, but I trust I shall shortly see thee and we shall speak face to face." There are similar texts which convey explicit messages with a few words of wireless.

"We are just a bit proud to be able to say that the Canadian Pacific was the first

Canadian company to establish a daily all-Canadian news service for its fleet of steamships on the Atlantic, and that it maintains this exclusive feature for its passengers. The results have been very satisfactory. This news is made up daily by the Canadian Pacific, at Montreal, from the latest press dispatches from all over the Dominion and is transmitted to all Canadian Pacific ships on the Atlantic. The Canadian Marconi Company erected a special press station at Louisburg, Nova Scotia, for the purpose of transmitting such news.

"The Canadian Pacific is giving much attention to the importance of providing the latest radio direction-finding equipment on its ships, by means of which the position of a steamer may be quickly and accurately determined."

Of course the public appreciates the fact that radio programs are free, but broadcasting free verse is carrying generosity too far.—"The Evening Telegram," New York.

L. H. DONNELL MFG. CO.
Dept. B, Box 70 Ann Arbor, Mich.

What is the power of the Naval station, NAH, New York? Does this station maintain a C-W transmitter? Is this the only station operated by the United States Navy near New York?—David Lloyd Jones, Fall River, Mass.

The power at the Naval Station at New York is 5 kilowatts. There is a 3-kilowatt radiotelephone transmitter in the station which can be used for straight C-W, interrupted C-W, and, also, for voice production. This station is operated at the remote control station, New York, and is not the only United States Navy station near this city. There is a radio station at Sayville, L. I., and another at Amagansett, L. I., operated by the Navy but under the remote control station in New York City. The Navy also maintains four radio-compass stations at Sandy Hook, N. Y., Mantoloking, N. J., Amagansett, L. I., and Rockaway, N. Y. The last-named station is for compass work with the airplanes.

Will you please publish a diagram showing the method for using a buzzer for detecting the sensitive spot on a crystal detector?—RADIO WORLD Reader.

Diagram of simple method used in the selection of detector crystals, requested by "Radio World Reader." The same hook-up can be employed to assist in the adjustment of the set.

The accompanying schematic diagram shows the method of employing a buzzer with a tuning coil.

What is the relation between the length and height of an aerial?—Frank S. Smith, Omaha, Neb.

For receiving it is not necessary to have the aerial at such an excessive height. About thirty feet will do very nicely. An aerial about 100 feet long is necessary for receiving broadcasting stations.

I have a set consisting of a single-slide tuner with a pair of 2200-ohm phones, 3-wire aerial 35 feet long and 45 feet high. My aerial runs straight with the telephone lines, the distance from them being about two inches. Will this interfere with my set? At times I have trouble hearing voice from the telephone lines. What can I do to hear distinctly and eliminate interference?—Radio Student.

Answering your first query: Try and see if you can run your aerial in one stretch of about 100 feet. One wire aerial is far better than a number at a shorter distance. When erecting your aerial run it in such a manner that it will be at right angles to the telephone wires. If possible keep it clear from them as much as possible. The further you get away from telephone wires the better will be the results. Don't place your ground wire on the same ground as (Continued on following page)

If you did not get copies of Radio World No. 1 to No. 26, send us \$3.00. Or we will send you this paper for one year, (\$6.00 for 52 issues) and start it with our first issue, which will be mailed you as soon as possible after receipt of order.

Answers to Readers
(Continued from preceding page)

that of the telephone ground. Seek a new ground, preferably an outside ground. With all this in view signals should respond, provided you have a good crystal detector. However, we advise you to read and digest the article entitled "Why the Open Antenna Is Best for the Radio Listener," by C. D. Wagoner, in RADIO WORLD, Vol. II, No. 2, dated October 7. This is very important.

Why can't I hear the broadcasting with a one-slide tuning-coil 4 inches in diameter wound with approximately 260 turns of No. 28 wire, phone condenser, phones, detector of the crystal type, and a 1-wire aerial 80 feet long. The lead-in is about 45 feet. What should the wave-length of this set be?—Milton Semken, Salt Lake City, Utah.

It seems that your aerial is a bit short for good results. Another thing: the size of wire you are using is too small. Its resistance is too high. This wire does not operate efficiently in a tuning coil. Too many turns have a bad dead-end effect. As your set stands the maximum wave should be about 3000 meters and the minimum about 200 meters. You will have poor results on the smaller waves. You should either make dead-end switches or employ a shorter coil for the 360-meter wave.

Will you publish a hook-up of a receiver that will respond to long waves having the use of regeneration?—Harold Yankton, Detroit, Mich.

Regenerative circuit employing tickler coil and loading coil for long waves, requested by Harold Yankton, Detroit, Mich.

The accompanying schematic diagram shows the proper connections for receiving the longer wave-lengths in a receiver. All connections should be carefully inspected before any attempt is made to listen in on the set.

I am enclosing diagram of circuit used in my receiver. I would like to see a hook-up whereby one stage of radio frequency is employed with such a circuit. Have tried several hook-ups and this one gives the best results.—Thomas E. Cecil, Erwin, Conn.

In RADIO WORLD, Vol. II, No. 2, dated October 7, this circuit was fully described by Mr. C. White in his article "Constructing a Radio-Frequency Regenerator."

Can you show by diagram how the wiring is accomplished on the tuner in RADIO WORLD, No. 26, dated September 23, page 13, Figure 5? Show the number of turns and taps thereon.—M. L. Proctor, Valdosta, Ga.

This information can be had only from the Bureau of Standards, Washington, D. C., the designers of this particular receiver.

A broadcasting map for 15c. That is, a complete broadcasting map appeared in RADIO WORLD, No. 8, dated May 20 Mailed on receipt of 15c. Radio World Company, 1493 Broadway, New York City.

Big Eastman Pipe Organ Pleases Radio Listeners

EXPERIMENTS in connection with the operation of the Eastman School radio broadcasting station WHAM, Rochester, N. Y., resulted in the broadcasting of one of the finest concerts ever heard.

As radio enthusiasts have waited anxiously for the station to announce a schedule of music, experiments have been going ahead night and day in the hope that the auxiliary equipment would make possible the broadcasting of the excellent musical features of the Eastman Theatre.

Walking into the sending station yesterday morning, Arthur Alexander, director of the Eastman Theatre Orchestra and a member of the Eastman School of Music faculty, who has had years of experience in radio activities, suggested the elimination of some of the auxiliary equipment used to relay the music from the theatre to the sending station. It was agreed that it would be wise to try and simplify the equipment. Mr. Alexander directed the activities of the radio staff, and the experiments proved successful.

Those who were "listening in" were treated to a real surprise when the peal of the big Eastman pipe organ was heard distinctly and with little or no distortion. This surprise was magnified a hundredfold, however, when the strains of the fine orchestra were heard.

Football by Radio

An interpretation of this year's football rules and a general discussion of college athletics will be given from WGY, Schenectady, N. Y., on Thursday night, October 12, by Lieut. Elmer Q. Oliphant, director of physical education at Union College. Lieut. Oliphant is considered one of the greatest athletes ever developed in an American university.

He is the only graduate of Purdue University, or West Point, to win four letters, making the varsity teams in baseball, football, basketball, and track. He was All-American choice for half-back in 1915, 1916, and 1917. In 1915, he was All-American choice in basketball and as catcher in baseball. The address by Lieutenant Oliphant will be part of a "college night" program to be put on by the instrumental and glee clubs of Union College. The program will include the songs and cheers of many colleges and universities. Dr. A. R. Brubacher, president of the New York State College for Teachers, will also speak on "Tradition in College Education."

Rain by Radio

RAIN will come and go at your own will, in the future: says "The Gazette," Falls, New York.

This possibility is another prediction for the field of radio.

It was made by Marconi, the famous inventor, at his recent visit to America. Other radio engineers also have expressed the opinion that the control of rainfall by radio is possible.

Just as a bolt of lightning and thunder are forerunners of a rainstorm, says Marconi, so might radio produce the same result.

"We undoubtedly will accomplish this wonder some day," he says. "And then we will become the lords and masters of life on this planet. We will be able then to obtain any amount of power almost without effort.

"All the work will be done by the sun. Man will merely press the button.

"The developers of water power and of the radio transmission of electrical energy produced by water power will become exporters of electrical energy to less fortunately situated countries."

IMPORTANT NOTICE:
While every possible care is taken to state
correctly matters of fact and opinion in technical
and general writings covering the radio field, and
every line printed is gone over with a scrupulous
regard for the facts, the publisher disclaims any
responsibility for statements regarding questions
of patents, priority of claims, the proper working
out of technical problems, or other matters that
may be printed in good faith and on information
furnished by those supposed to be trustworthy.
This statement is made in good faith and to save
time and controversy in matters over which the
publisher cannot possibly have control.

**SCR-79-A, Radiotelegraph
Set Heard 2,700 Miles**

IN testing out the radius of one of its
standard radiotelegraph sets, desig-
nated as SCR-79-A, the United States
Signal Corps has established a new rec-
ord of transmission between 1,175 and
2,700 miles.
A 79 set was temporarily installed in
the headquarters of the 9th Corps Area,
San Francisco, with the call WYCH, and
communication was undertaken with
Army transports on the Pacific. On one
occasion, the "Sherman" reported having
heard the signals from WYCH while she
was 700 miles west of Honolulu—a dis-
tance of, approximately, 2,700 miles.
Other signals were exchanged between
the Signal Corps station and the "Buford"
over a distance of 1,550 miles, and with
the "Sherman" again when she was 1,480
miles away.

This record is considered very remark-
able for a set designed for under 100
miles, although communication was not
maintained for any length of time and
interference was at a minimum.

**Motorcycle Recharges
Battery**

A LONG spin on his motorcycle is
necessary for Stanley E. Schnabel,
Allentown, Pennsylvania, every time he
wants to listen-in on his radio set. In a
recent letter to WGY, Schenectady, New
York, Mr. Schnabel, who is the Associated
Press operator for the "Chronicle and
News," says that he uses his motor-
cycle battery to furnish current for his
wireless outfit and the battery generally
lasts one evening. He recharges on his
trip to and from work, but this isn't suffi-
cient for the night's fun at the radio re-
ceiver, so he takes a long spin after sup-
per to get enough "juice" for the set. He
is now planning to take his set along
with him in his side car, put up a tem-
porary aerial and ground, and listen in.
In this way he can start up the motor-
cycle every time the battery gets weak.

Otherwise, Nothing Happened!

EDITOR RADIO WORLD: Being a "bug" interested in your "ideal" magazine, I take the liberty to forward you this "Hash Comic Story." I met my girl the other "nite," and as I was walking down to "receiver," her face "sparkled" with the "air" of joy, but I missed my "balance" and hit the "ground" and "2nd step." 'Twas some fall to "meter." As I fell, I heard the "crystal" of my "watch" break as I "tapped" it on the "dial." While I felt my "aerial" for bumps, who did "I-C" wandering down the avenue, a motor-car "buzzing" behind him, but "Cur-Rent" the villian. It was he who put the "damper" on my "radiation" with his sister Miss "Galena."

As he passed I "gapped" as to not "c q" was passing, my lady friend was telling me how "delightful" she was over the "vacuum" sweeper I gave her for her birthday.

Arriving at her home, her dad asked me to listen in on new set he had "resently" bought for "73" smackers. I did and was overjoyed.

Just then the clock "registered" three o'clock "am (p) here." It was the "signal" for me to "sign off" for the "nite." As "I-C"-was "going out" I realized that Mr. "Cur-Rent" was awaiting me with an "insulated" piece of "lead" in his "fist." I "howled" like a "squeak box" and the "copper" on his "feed-back circuit" asked me, "How do you come over." He did not know my "location." The cop said he would "charge" me with vagrancy. I told him I'd put the "Ohm's Law" on him.

He let me "pickup" my hat and told me to go "straight" home. So I took his advice and "dashed" "ohm" to my mother.—Doug Tremper, Brooklyn, N. Y.

Pictures and Facts About Armstrong Amplifier

Radio World has published a number of pictures, diagrams and descriptive articles regarding the New Armstrong Super-Regenerative Amplifier. The numbers containing this material are dated June 24, July 8, July 15, August 5 and September 18. They will be sent postpaid on receipt of 15 cents each, the five copies complete for 75 cents. Or you can subscribe, \$6.00 year; \$3.00, six months, and have your subscription start with the number dated June 24. RADIO WORLD CO., 1493 Broadway, New York.

22 to 500 Volt "B" Batteries

Lasts Five Years

Recharged From Any Lamp Socket

The Sidbenel is a Storage "B" Battery that will last five years of constant use without replacing parts.

It will give continuous service for at least six months before it becomes necessary for recharging. It can then be recharged in a few hours to its original capacity, all ready for another six months use.

A Sidbenel Storage "B" is something every radioist needs. Think of the money saved by not using dry "B" batteries, which are of no use after they once become discharged.

The Sidbenel pays for itself in six months. It is so ruggedly constructed that rough usage will not harm it. The container is one which is of genuine hard rubber, molded into ten compartments. Size 2½" by 3" by 4¼". Every inch of Sidbenel "B" is constructed under our own patents. The plates are especially treated with a newly discovered chemical that eliminates howling and screeching, so commonly found in any other "B" battery.

The Sidbenel "B" is shipped to you partly assembled—all you need to do is connect the plates together, and this takes but ten minutes and is most simple, as instructions are furnished with each battery.

Guarantee:—A two-year written guarantee is given with each Sidbenel Storage "B" Battery. This is your complete protection.

For recharging we furnish a rectifier for AC which costs \$0.25 extra. DC current requires none. Complete with directions:

One Unit, 23 volts.....	\$3.85
Two Units, 44 volts.....	\$7.50
Five Units, 115 volts.....	\$17.50
Eleven Units, 250 volts.....	\$36.50
Twenty-two Units, 500 volts.....	\$65.00

State of New York,
County of New York, ss:
Before me, a Notary Public, in and for the State and County aforesaid, personally appeared Roland Burke Hennessy, who, having been duly sworn according to law, deposes and says that he is the Editor of the Radio World, and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and control, if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are: Publisher, Hennessy Radio Publications Corporation, 1493 Broadway, N. Y. C.; editor, Roland Burke Hennessy, 1493 Broadway, N. Y. C.; managing editor, Robert Mackay, 1493 Broadway, N. Y. C.; business manager, Fred S. Clark, 1493 Broadway, N. Y. C.

2. That the owners are: (Give names and addresses of individual owners, or, if a corporation, give its name and the names and addresses of stockholders owning or holding 1 per cent or more of the total amount of stock): Hennessy Radio Publications Corp., 1493 Broadway, N. Y. C.; Roland Burke Hennessy, 1493 Broadway, N. Y. C.; M. J. McArthur, Statler Hotel, Cleveland, Ohio.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of

FOR SALE—Regenerative sets with detector. Complete with tube and B Battery, \$35.00. With one stage, \$50.00, complete with tubes and batteries. Satisfaction guaranteed. Edward Bittner, Schuyler, Nebraska.

Exchange jolly interesting letters through our Club! Stamp appreciated. Betty Lee, Inc., 423 Broadway, New York City.

ISSUES OF RADIO WORLD from April 1 to Oct. 7 (77 numbers) for 15c a copy, or the whole lot for \$3.15. Or send us \$6.00 for one year and start with the first number. RADIO WORLD, 1493 Broadway, New York.

DO YOU USE A CRYSTAL DETECTOR? ARE YOU MAKING A CRYSTAL RECEIVER? Increase the efficiency of your crystal detector 1,000 per cent by using a "PT" Ultra-Sensitive Contact. Of special gauge and alloy. Makes and holds a quick, ultra-sensitive, stable adjustment. Using galena, you may pound panel or table without disturbing sensitivity in slightest. Proved practical on shipboard by an old-time Marconi operator. Using a "PT" Contact on galena, Arlington (NAA) was brought in clear at 3,300 miles (below the Equator); and Arlington came in loud at 2,200 miles (off Dutch Guiana). In both instances, nearby ships using vacuum tubes were unable even to hear NAA. As to stability, Cape May (WCY) was worked over 1,000 miles, sending right through crystal with 2 KW spark, without affecting detector's adjustment. Replace your old insensitive unstable contact with one which will hold its adjustment in addition to giving louder signals and music. Indispensable for pocket sets and crystal detector-bulb amplifier outfits. A novice can install. "PT" Ultra-Sensitive Detector Contact, with instructions, twenty-five cents coin or M. O. "PT" CRYSTAL CONTACT CO., Box 1641, Boston 8, Massachusetts.

total amount of bonds, mortgages, or other securities are: (If there are none, so state.) None.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear on the books of the company but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear on the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association, or corporation has any interest direct or indirect in the said stock, bond, or other securities than as so stated by him.

5. That the average number of copies of each issue of this publication sold or distributed, through the mails or otherwise, to paid subscribers during the six months preceding the date above shown is..... weekly. (This information is required from daily publications only.)

ROLAND BURKE HENNESSY, Editor.

(Sworn to and subscribed before me this 30th day of September, 1922.)

Notary Public, New York County, New York County Clerk's No. 304, New York Register's No. 4223. Commission expires March 30, 1924.

Note—This statement must be made in duplicate and both copies delivered by the publisher to the Postmaster, who shall send one copy to the Third Assistant Postmaster General (Division of Classification), Washington, D. C., and retain the other in the files of the post office. The publisher must publish a copy of this statement in the second issue printed next after its filing.

YOUR PHOTO IN THIS PAPER ATTENTION AMATEURS!

Have you built your own receiver?

Are you experimenting with any particular hook-up?

Are you improving your set?

Are you doing any interesting constructive work in radio?

Why not share this knowledge with your thousands of brother fans who read RADIO WORLD every week?

We want pictures of receiving sets with descriptions of how you overcame some difficulty, or of any additional part or unit that you have added to obtain better results. These are the things that, probably, the other fellow is looking for. Send in your information; pictures or whatever you have done to improve the art.

Remember the beginner is looking for them.

We intend to print in this paper, each week, pictured information and description of value to radio amateurs. If you have found a newer or better way of doing anything, don't keep the secret but tell it to your thousands of brother fans.

Send in a photograph of your set with or without accompanying diagrams and measurement. State whether you figure in the picture yourself, or not, and without any expense whatsoever to you we will make an engraving and publish it. Be sure to write your name and address plainly on photograph.

Send in your picture at once, or if you have not made a set or done anything else in making radio material, tell the boy next door all about this offer.

Address: Technical Editor

Broadcasting Suffering in Germany

BROADCASTING in Germany seems to be suffering from an overdose of "verboten," according to reports reaching the United States Department of Commerce from Vice-Consul Nathaniel B. Davis, at Berlin, says an International News Service dispatch from Washington. With apparatus costing a great deal of money, and with Government restrictions weighing heavily, the amateur does not enjoy anything like the freedom of activity that obtains in this country.

The German Post Office Department, which is in charge of all radio communication, permits private companies and individuals to build their own plants only on payment of a license fee. Ordinarily, the department itself installs the plants; it also rents receiving sets for 2,500 marks a month.

Orange Label Tea

Special 10¢ Tins

So good,
you ask
for more!

Enjoy a cup of *good* tea—let it greet you at breakfast, cheer you at luncheon, revive you at dinner and promote refreshing sleep.

Also sold in 1 lb., 1/2 lb. and 1/4 lb. TINS

GRAND PRIZE San Diego 1916

—and now
harmony replaces discord!

MUSIC—clear as a bell; speech—so that every word is marvelously distinct; jazz—in un-interrupted syncopation; opera—with that transcending, full-toned quality which brings its remarkable beauty into strong relief.

Until you have actually heard reception through RADIOBATS "A" and "B" you cannot imagine how wonderful radio can be—and there *is* no way to hear it, till these epoch-making, new-principle batteries are hooked in.

This sort of radio reception *is* a matter of *batteries*. Elimination of most *noises* is a matter of batteries, rather than static or other interference.

RADIOBATS "B"—as well as "A"—are *leak-proof* because they have the *only solid electrolyte*; and they are more economical, because, like "A" Batteries, they are indefinitely *rechargeable at home*.

These noises are caused by the *irregular* voltage output, natural in ordinary "B" batteries. Where the current output becomes unvarying, these noises cease—and this marvelously clear and life-like reception results.

Send now for the intensely instructive booklet "The permanent Power Unit for Radio" and send your dealer's name and address so that we may arrange an immediate demonstration. There is absolutely no obligation.

And it is because RADIOBATS "A" and "B" are the only batteries which act as radio batteries *should*, that we urge you to listen to a demonstration at your dealer's.

Editorial Announcement!

RADIO WORLD Suggests

National Radio Week Nov. 26 to Dec. 2, 1922

REASONS:

To create greater public interest in radio. To increase the output of manufacturers. To increase sales by distributors and dealers.

To make possible a still greater volume of Christmas-gift purchases.

PLAN OF CAMPAIGN:

Request interest and space of radio editors throughout the United States and Canada for a National Radio Week.

Remind fans that Radio parties would be pleasant and profitable, and that during that week they should invite friends—especially those not acquainted with radio—so that they may listen in with their hosts.

Bigger and better window and counter displays during National Radio Week.

Have you, as a manufacturer, distributor, or dealer, or fan, any other suggestion to make?

Suggestions forwarded to Radio World on this important event will be received gladly and accorded attention in the editorial columns of Radio World.

The suggestion now is that NATIONAL RADIO WEEK be held from November 26 to December 2. (Thanksgiving Day falls on November 30.)

Why should not radio, bringing music, entertainment, and information, and supplementing the official Thanksgiving messages cheer from our President and the Governors of States, be made an important part of the wholesome activities of Thanksgiving Day? These greetings, coming from men of our country prominent in science, literature, the stage, and the church, and heard through the new medium of radio, will give an added importance to their utterances.

Write and tell us what you will do to help along National Radio Week

Address at once: National Radio Week Editor, Radio World, 1493 Broadway, New York

Be a Booster for National Radio Week!

Important Improvements in Radio Receivers

By C. White, Associate A. I. E. E.

SO busily are we engaged in trying to invent new circuits that we often forget the possible improvements we can make in the construction of the average radio-receiver. Fortunately there are many manufacturers who, realizing that amateur radio popularity is here to stay, are actually employing scientific research to better their apparatus. Still, nevertheless, there are a vast majority who are satisfied to build anything that just works—and that's all. But, the amateur who builds his own outfit is subjected to the same dangers as the unscientific manufacturer, in that he is often deceived into thinking that if the set works it is O. K. in every respect and represents the height of efficiency.

There is not a man who would knowingly put a poorly constructed appliance in his home, but there are amateurs who care for nothing save to hear a sound over their sets, and they will quickly say, "Why worry" if something is at least heard. On the contrary, a majority of radio fans are electrically inclined and are beginning to seriously consider if they have outfits that present the acme of electrical perfection.

The first consideration in any electrical circuit is to cut all losses as low as possible without incurring too much expense. The average dividing line is generally the point at which scientific perfection and economical construction costs are just about balanced. In other words, if a certain additional improvement saves less than the cost to make the same then it is foolish to incorporate such an alteration. In most every radio circuit, variable condensers of the rotary plate, air insulated, type are employed. These condensers as generally constructed for radio work have a rather high loss of energy, owing to the fact that the air gap is relatively large. The amateur will find that, in the ordinary regenerative and non-regenerative circuit, it is far better to use a fixed mica condenser, shunted with a small three-plate air condenser as a vernier. By so doing, he will not only cut down the initial cost of installation, but will also raise the efficiency of his set, since a mica condenser is more nearly a perfect condenser. For most tuning circuits, a mica condenser of .0005 microfarads with a large three-plate vernier will be

about the right size. If .0005 mfd., is too much capacity another mica condenser of .00025 mfd., may be placed in series with it. The cost of such an arrangement is several dollars cheaper than a corresponding 23-plate variable condenser, yet it is more compact, sharper in tuning and, electrically, more efficient. It is even sometimes more economical to use the better scientific methods.

The resistance of a radio circuit is often the least consideration. To the average man, any kind of copper wire is good enough. Generally he will employ No. 22 or No. 24 S. C. C., or D. C. C., magnet wire for his coils and No. 18 wire for hooking-up the component parts of the set. While there is nothing radically wrong with the use of the latter, still for the coils it would be far better to employ a wire made up of the smallest size of S. C. C. magnet wire procurable, wrapped together in the fashion of the strands of a rope. The number of strands will naturally depend on the size of one strand. By so doing, the effective resistance of the circuit to radio and audio-frequency waves will be greatly cut down. A single wire containing the same amount of copper will offer the same resistance to direct current; but with respect to alternating current, its effective resistance will be much more owing to the tendency of high-frequency currents to crowd to the outer surface of the wire and not use the center. By using wires of smaller diameters in parallel and insulated from each other, this so-called skin effect can be reduced. The type of wire just described may be purchased at radio stores. Naturally, if the amateur so desires he can wind these strands if he has the time, but it is a slow and cumbersome job without the aid of the proper mechanical appliance.

Shielding is another point that has been seriously neglected on amateur apparatus—in many cases by the amateur building his own set; in others, by manufacturers of cheap outfits. Any cabinet-mounted set should first be shielded from the body capacity of the operator. This is accomplished by lining the interior of the cabinet with fine copper-screening. Most people think that after this has been done

Have You a "Radio-Regulated" Watch?

(C. Kadel & Herbert News Service)

The up-to-date jeweler regulates the watches left in his charge by radio, because the time of the day sent from Washington, over the ether waves, is so absolutely correct there cannot be the slightest variation of even a fraction of a second. The engraving shows Simon Rimler, a New York jeweler, and his radio time-receiver. Soon the boast of the man who knows that his watch is exactly on the second will be: "Mine is a radio-regulated watch."

Be Sure of Your Ground Connection

By Fred Chas. Ehlert

THERE are few beginners who are dabbling in radio who realize sufficiently the prime importance of a good ground connection. To many, the principal part of the receiving station is the aerial; whereas, if the truth were known, the ground is every bit as vital to good clear and dependable reception as the aerial. Altogether too many amateurs spend hours in erecting an antenna, endeavoring to see that the wires do not touch other objects and inspecting joints to see that they are securely soldered. But the ground is left until the last and is then made by twisting a few turns of bare wire around the most convenient pipe. The accompanying simple sketch explains the essentials of a radio receiving-station.

The radio waves as they pass through the air and the ground are oscillating in character. This means that they first go from the transmitting aerial to the receiving aerial, then to ground and from there back to ground of transmitter. After the cycle is completed, they reverse their direction and travel down through the earth of the transmitting set over to the ground connection of the receiver, up the antenna, and back through the other to the transmitting antenna. This scheme of going first one way and then the other is made possible because of the condenser effect. It is obvious that the ground must play its part as satisfactorily as the aerial. Whatever applies to the aerial applies likewise to the ground.

For instance, the aerial is made up of copper wire of fairly good size. No. 14 will give good service. This is necessary to reduce the antenna resistance.

Similar precautions should be taken with the ground. It should be made to present as low a resistance as facilities permit, so the minute radio currents may pass down the antenna through the set and thence to ground without being forced to overcome obstacles. It is safe to say that most grounds could be improved, but this is not always advisable because of the ex-

Schematic diagram of a simple receiving station showing how the impulses—on the signals or sounds—pass from the earth to the antenna and then back to the earth.

(Continued from preceding page) the screening is one hundred per cent perfect. This is not the case, because we have only shielded our apparatus against external capacity effects and nothing at all has been done to cure the trouble originating from internal inductive interferences. Each component part of the set should in addition have a copper screen around it. The advantage of so doing cannot be fully appreciated in a small single-circuit receiver; but when the more complex circuits are used and the coils are mounted compactly, mutual inductive interference between coils is sure to occur and the only remedy is to shield each group of coils that are to be mutually coupled from the adjacent group. Care must be taken to see that none of the connecting wires become grounded on the shield; and all shields should be grounded—that is, connected electrically to the ground terminal of the outfit.

Another element that the amateur gives but little attention, is the selection of his vacuum tubes. The average man is of the general opinion that, for receiving, there are two types of tubes only: the UV 200 and UV 201. This is erroneous. There are other tubes for reception, although their characteristics are much different from those of the ordinary types. The power, or transmitting, tubes have proved very satisfactory in this connection. In fact, they give very much more volume per tube than the others. This is especially noticeable in the regenerative re-

ceiver. The marked advantage of power tubes for reception is the increase in volume and the absence of hissing, such as the soft or gaseous tube is accustomed to do when operating at its critical point. The objection to the use of the power tube as a detector and amplifier is the necessity of securing high-plate voltage. Small-size B batteries in series is not an altogether satisfactory method of obtaining the necessary potential, since the current drain on the same is quite heavy. Manufacturers of B batteries are providing a larger size battery for this purpose. No matter what type of tube is used, it is always satisfactory to use some form of vernier rheostat for precise adjustment of the filament current.

In choosing a circuit, always give a double circuit first preference over a single circuit because the former is better in its selectivity. After you have chosen your circuit and are ready to construct, bear in mind certain facts concerning the general improvement such as I have explained. It may cost a little more to put all these improvements on your receiver; but you will find that they are fully worth the money, time, and trouble. When purchasing or placing an audio or radio-frequency amplifying transformer in your receiver, be sure to see that it is shielded, especially if more than one stage of amplification is used. Buy a good standard make of transformer, because transformers may "howl," even if shielded, if their coupling is too critical.

pense involved. A heating system may or may not make a good ground. The chances are against it; but if the receiving set is connected with the earth by a connection on a radiator, the oscillating current must overcome the ohmic resistance at each pipe joint.

If the ground connection is made to a gas pipe, the beginner may find that he has no ground at all. For the protection of their patrons, gas companies, as a rule, insert a wood or composition pipe-insulator somewhere between the gas meter and the first burner. If the amateur discovers one of these insulators, he should not overcome the difficulty by bridging the insulator with a piece of heavy wire, as he is then nullifying the good work of the gas engineers. Instead, the ground wire should be carried beyond the meter before attaching to the pipe.

How Radio Was Installed in Our Home

By Hattie Briggs Hartman

A FEW days ago, a motor-car stopped in front of our home. On the seat, by the driver, was a curious box. Before we were able to decide what it was, an electrician from a neighboring town jumped from the car, dashed up to the porch and announced that he had come to install a radio for us! In spite of our protests, he signaled his helper, and after asking us if we minded having a wire fastened to a tree at one end of the grounds, proceeded to install his magic machine so quickly that it seemed easier to permit him to proceed than to try and curb his enthusiasm.

A wire about the size used for telephones was fastened to a maple tree about thirty feet from the house; the other end was fastened to the eaves on the second story. An insulator was arranged at each end of the wire, and another wire of the same size was dropped down over the edge of the porch. This wire was fastened to the machine.

The men then began to look for the best way to use the ground wire, and decided that it would be feasible to bring the water pipe in the kitchen into play for that purpose. A small wire was run from the

front porch, through the living room and dining room, over the tops of doors and wall molding, into the kitchen. There it was strung to the pipes which went up to the bath-room and so on down to the water pipe where it enters the kitchen from out-doors. The wire was no larger than medium-sized linen thread and was up so high that it did not interfere in any way with the occupancy of any of the rooms.

The electrician rushed back to the porch, placed the jar of flowers which stood upon the porch-table aside very hastily, and put the radio machine on the table, under the hanging wire which came from the upper porch. This was fastened to the rear of the box, and the ground-wire was also adjusted. A battery stood upon the floor near the table and as the wires from the machine were snapped into place, to connect the battery, lights were visible inside the box which constituted the machine. The machine was about 30 inches long and 14 x 14 inches the other way. At the lower right-hand corner there was a knob, which, when turned just right, brought sound to the proper

degree of clearness. The expert adjusted the horn in its proper place, manipulated the knob, turned two small dials which were at the side of the box and, in a moment, cried, "We have it!"

He listened a second longer, jerked the head-set from his ears, and turned with a satisfied expression as he looked at our bewildered faces. In the shortest space of time imaginable, a burst of music came to us from Washington, D. C., and we were listening to one of the most famous bands in the country. Our home is at least six hundred miles from Washington. It was the most entrancing music we had ever listened to and we all sat with taut nerves, wondering whether it was really true or if the "city man" were playing a trick on us.

It was rather a shock to us when the announcer gave the name of the band. We knew we had been listening to real music and not to a reproduction on a phonograph disc. Our visitor manipulated the discs a few seconds, and exclaimed: "Here is something!" At once we were listening to an orchestra in Pittsburgh. At the end of an overture familiar to every music lover, we were ready for anything which might come to us; for we knew that it was coming to us through space—over vast stretches of country. We called in the neighbors by telephone and, in a short time, the porch was filled with a wondering audience.

At ten o'clock we set clocks and watches by radio. A few moments after that, we were listening to a college glee-club in Wisconsin. We caught Newark, New Jersey, and heard a famous tenor. Later we heard a Shakespearian recitation. It was an adventurous evening; sitting on our front porch and hearing voices from the air!

Sunday afternoon a sermon came to us from Rochester, New York. We heard it as plainly as if we had occupied a front pew in the church. We were rather awe-stricken to hear the earnest message from the lips of a man of God so many miles away from us. The choir was wonderful. That same evening we had a treat in listening to a lecture on the City of Albany. The bed-time stories sent out from the broadcasting stations might have easily come from the lips of a mother in her own home while coaxing her babies to sleep.

Bulky Loose Coupler of 12 Years Ago and the Vario-Coupler of To-day

(C. Kadel & Herbert News Service)

Compactness is the watchword in radio as in all other up-to-date matters. Mr. F. Clinton (right) is holding one of the old, massive loose-couplers, popular twelve years ago. Mr. W. Guillet (left) is showing, in comparison, the modern vario-coupler which has replaced it. The big instrument is on the way to the scrapheap.

One-Tube Regenerator Hook-up for Loud Sigs

By Harold Day

Schematic diagram of a set capable of receiving signals of great volume. It is known as a two-variometer regenerative-type receiver, and it will pick up short wave-lengths of the broadcasting stations, continuous waves, interrupted continuous waves, and also damped waves. All of these may be received on this machine, owing to the feed-back in the plate circuit. Drawn by S. Newman.

WHAT should I do to my set that will enable me to hear the broadcasting stations with much more volume, or, as they say, louder signals?

This question I am asked most every day. Here is the answer:

There are many circuits which may be tried out, but most of us don't like to dabble with hook-ups with which we are not familiar. The above is a hook-up of a one-tube circuit which will surprise any operator who dabbles with it. There is nothing complex about it—it is a plain, simple hook-up. No trouble should be experienced with a good aerial and ground. The parts need-

ed for this set may be purchased at most any radio shop. They consist of two variometers, one variometer, one tube socket and detector vacuum-tube, one vernier rheostat, two switch knobs and about a dozen contact points.

The wiring diagram is clearly shown. Care must be exercised to see that the proper connections are made. In the illustration, six connections, or binding posts, will be seen at the left. They are two for the A, or storage, battery; two for the B battery of 22 volts, and two for the connection with the telephones. In connecting up the B battery, one must be careful that

the plus side is connected to the plate side of the tube. If this connection is not correct, signals will not be heard.

There are two variometers, one in the grid circuit and the other in the plate circuit. The variometer in the plate circuit tends to tune in and feed back into the grid the added voltage of the plate circuit. The set then becomes what is called a regenerative set. As all regenerative sets generally are hard to tune, it will be noticed that this type receiver is very simple to operate. Due to the self-amplifying feature of the set, signals of satisfactory volume will be experienced.

Another Radio Myth Exploded

By C. D. Wagoner

ANOTHER myth to be exploded. Many people have the idea that an antenna attracts lightning, that it is dangerous to have it erected near the house. When their attention is called to, possibly, the electric-light wires crossing the street and coming into the house overhead, or the telephone wire running in a long span from a distant pole, the answer often is, that *these* wires are insulated, and hence lightning will not strike them!

This would be laughable if it were not so often heard. Lightning, striking through thousands of feet of air, the best insulator there is, would not bother much about an eighth of an inch of rubber surrounding a wire. The fact is, that lightning is just as likely to strike the power wires as it is the antenna. Yet we do not often hear of accidents due to lightning coming into a house by the electric-light feed-power wires.

Do not understand me to say that lightning *will not* strike the antenna, or the power wires either. If lightning makes up its mind to strike in a given locality, it is going to strike, and it is as likely to hit the house or the wiring inside it as any other point. As a matter of fact, a well-installed antenna with correct grounding device—described later—actually helps to *prevent* the house from being struck, in that it "drains off" the charges.

Broadcasting Increases Five-Hundred Per cent in Past Year

Stations Now in Every State—Additions up to Going to Press

WASHINGTON, D. C.—There were 546 broadcasting stations in the country on October 5; one or more in every State of the union. These stations supply radio enthusiasts with all the entertainment, news, governmental data on weather, agriculture, health and other subjects they may listen to all day and far into the night. But the total of 546 stations is literally too great, and the stations are not well distributed, according to Department of Commerce officials. Most of the broadcasters are located in the East and Southeast, where time schedules must be employed to avoid interference. The public would be better served, it is held, if there were fewer stations and they were more widely distributed or located in proportion to areas and population. Five hundred and thirty-five stations are broadcasting on 360 meters, the balance on 400 meters.

Sifting of Stations Needed

"What is needed now," one official explained, "is a sifting out of the lesser stations, which are not rendering satisfactory service and popular entertainment, so that the radio public may listen in to good music, authoritative statistics, and current news." The creation by the department of the Class-B license, granted to only the superstations, will guarantee high-class entertainment and excellent radio service, since those stations are granted authority to use a special wave length of 400 meters. There are eleven of these stations located in seven States, making good programs, without mechanical music and cheaper forms of entertainment, available in practically all the eastern and some central States, where the fans listen in on 400 meters, watching local papers for the daily programs.

The 535 stations operating on 360 meters will have to look to their programs, as public opinion will indicate which shall continue in service for any length of time. The operating expense is so high that, eventually, only the good ones with sound backing will remain.

In September, 1921, the Department of Commerce licensed WBZ, WJZ, and KDPM, three Westinghouse Electric stations, to broadcast at Springfield, Massachusetts,

By Carl H. Butman

Newark, New Jersey, and Cleveland, Ohio. They are still active today. During the next two months, October and November, the Detroit News, WWJ, and the Westinghouse station at East Pittsburgh, KDKA, were licensed, and then, in December the fun began. Twenty-three stations were licensed, January saw the addition of only eight, in February there were 24 new licenses issued; 77 in March; 76 in April; and, in May, the peak of the radio curve was reached with 97. Since then the number of licenses issued has fallen off slowly each month as follows: June, 72; July, 76; August, 50. In September but 39 stations were granted licenses. This, a government radio inspector says, is due to the fact that the saturation point is reached. There are enough regular broadcasters. Many of the larger, mostly the older, stations are seeking Class-B licenses, but not many such licenses will be granted, due to the qualifications laid down and the program requirements.

Broadcasting Now in Every State

With the issuance of a license in Laramie, Wyoming, every State in the Union now has one more broadcasting stations. As has been the case since the industry got a fair start, California still leads, having to-day, 66 stations, Ohio, follows with 35, and New York is third having 30. There were eleven licenses issued during the past week, as follows:

KFDA—Adler's Music Store, 5 watts, Baker, Oregon.

WMAV—Alabama Polytechnic Inst., 750 watts, Auburn, Alabama.

WRAU—Amarillo Daily News, 20 watts, Amarillo, Texas.

WMAU—Louisiana State Fair Association, 50 watts, Shreveport, La.

KFEC—Meier & Frank Co., 100 watts, Portland, Oregon.

WMAU—Paramount Radio Corp., 400 watts, Duluth, Minn.

WNAG—Rathert Radio & Elec. Co., 45 watts, Cresco, Iowa.

WMAQ—The Fair Corporation and The Chicago Daily News, 1,500 watts, Chicago.

KFBU—Bishop N. S. Thomas, 10 watts, Laramie, Wyoming.

WMAR—Waterloo Electric Supply Company, 50 watts, Waterloo, Iowa.

WQAQ—West Texas Radio Co., 60 watts, Abilene, Texas.

Few Broadcasters Have Quit

Of the 558 broadcasting stations licensed, twenty-six only have fallen by the wayside, so to speak, and some of those were deleted from the department's active list because of the amalgamations of two stations in the same district or the transfer of a station, in which cases the service did not stop. The broadcasting stations dropped or changed are as follows:

KOQ—Modesto Evening News.

KNR—The Beacon Light Co., Los Angeles.

WGNC—Orpheum Radio Stores Co.

WCAZ—Robert E. Compton, Quincy Whig Journal, Quincy, Ill.

WAAE—St. Louis Chamber of Commerce.

KZI—Irving S. Cooper, Los Angeles.

WGH—The Fair, Chicago.

WFAK—Domestic Electric Co., Brentwood, Mo.

WEAQ—Y. M. C. A., Berlin, N. H.

KGC—Electric Lighting Supply Co., Hollywood, Calif.

WAAT—Otto H. Taylor, Wichita, Kans.

WGM—Georgia Ry. & Power Co., Atlanta, Ga.

KSC—O. A. Hale & Co., San Jose, Calif.

WOC—Karlawa Radio Co., Rock Island, Ills.

KQL—Aron A. Klugs, Los Angeles.

KGB—Edwin L. Lordon, San Francisco.

WGH—Montgomery Light & Power Co., Montgomery, Ala.

WPD—Newspaper Printing Co., Pittsburgh.

KFU—The Precision Shop, Gridley, Calif.

WDW—Radio Construction & Electrical Co., Washington, D. C.

KDYD—Rocky Mountain Radio Corp., Denver, Colo.

WAAB—Times-Picayune Pub. Co., New Orleans.

WQB—C. D. Tuska Co., Hartford, Conn.

WAAF—Union Stock Yards & Transit Co., Chicago.

KOJ—University of Nevada.

Every Radio Set Has a Reliable Range

By John Kent

IT seems that the first question the average person asks when purchasing his collection of radio equipment concerns the relative range of such a set. The dealer eventually may answer this question by giving some attractive distance, or he may be more honest and tell his customer the limitations of the apparatus and the range that may be expected under varying conditions.

The range of any set, no matter how good or how poor, cannot be guaranteed. An estimate is no more than a guess. Two sets, identical in every respect, may have a widely different range when set up in different localities. You may have a set that gives very good results and you may move only a few blocks away and discover that your set is useless. This may be due to the fact that you were not able to erect as good an aerial in your new locality as in your old, or your ground may be not as good. Possibly there are high buildings about you that would cut off some of the waves.

Under given conditions, you can shortly ascertain the working or reliable range of your set. You will find that there are some stations that you can hear with, practically, the same intensity under almost all conditions. This distance you may call your "reliable range" although it may seem considerably lower than the range advertised by irresponsible dealers and manufacturers.

At times you may hear remarkable distances with satisfactory intensity, but these results cannot be depended on. Therefore, they must be classified under the variable range of your set.

There are many things which determine the range. Among them are time of day, atmospheric conditions, local conditions, circumjacent obstructions, topography,

and the nature of the aerial and ground. Reception of transmission can seldom be carried on over as great distances during the daytime as during the night. This is due, possibly, to the ionization of the air particles by the sun's rays, causing a partial absorption of the waves. Buildings with steel frames also ab-

sorb waves. Topography has a decided effect on radio. Waves travel much more readily over water than over land. Metal and mineral deposits sometimes causes absorption losses.

The importance of a good aerial and ground cannot be overestimated, as this greatly affects the range of a set. You cannot expect to get the same result with an indoor loop as with one outdoors.

To Study Radiotelegraph Signals

(Reprinted by General Request)

INTERNATIONAL RADIOTELEGRAPHIC CONVENTION

LIST OF ABBREVIATIONS TO BE USED IN RADIO COMMUNICATION

ABBREVIATION.	QUESTION.	ANSWER OR NOTICE.
PRB	Do you wish to communicate by means of the International Signal Code?	I wish to communicate by means of the International Signal Code.
QRA	What ship or coast station is that?.....	This is.....
QRB	What is your distance?.....	My distance is.....
QRC	What is your true bearing?.....	My true bearing is..... degrees.
QRD	Where are you bound for?.....	I am bound for.....
QRF	Where are you bound from?.....	I am bound from.....
QRG	What line do you belong to?.....	I belong to the..... Line.
QRH	What is your wave length in meters?.....	My wave length is..... meters.
QRJ	How many words have you to send?.....	I have..... words to send.
QRK	How do you receive me?.....	I am receiving well.
QRL	Are you receiving badly? Shall I send 20?..... for adjustment?.....	I am receiving badly. Please send 20. for adjustment.
QRM	Are you being interfered with?.....	I am being interfered with.
QRN	Are the atmospheric strong?.....	Atmospherics are very strong.
QRO	Shall I increase power?.....	Increase power.
QRP	Shall I decrease power?.....	Decrease power.
QRQ	Shall I send faster?.....	Send faster.
QRS	Shall I send slower?.....	Send slower.
QRT	Shall I stop sending?.....	Stop sending.
QRU	Have you anything for me?.....	I have nothing for you.
QRV	Are you ready?.....	I am ready. All right now.
QRW	Are you busy?.....	I am busy (or: I am busy with.....). Please do not interfere.
QRX	Shall I stand by?.....	Stand by. I will call you when required.
QRY	When will be my turn?.....	Your turn will be No.
QRZ	Are my signals weak?.....	Your signals are weak.
QSA	Are my signals strong?.....	Your signals are strong.
QSB	Is my tone bad?.....	The tone is bad.
QSC	Is my spark bad?.....	The spark is bad.
QSD	Is my spacing bad?.....	Your spacing is bad.
QSE	What is your time?.....	My time is.....
QSF	Is transmission to be in alternate order or in series?.....	Transmission will be in alternate order.
QSG	Transmission will be in series of 5 messages.
QSH	Transmission will be in series of 10 messages.
QSI	What rate shall I collect for.....?	Collect.....
QSK	Is the last radiogram canceled?.....	The last radiogram is canceled.
QSL	Did you get my receipt?.....	Please acknowledge.
QSM	What is your true course?.....	My true course is..... degrees.
QSN	Are you in communication with land?.....	I am not in communication with land.
QSO	Are you in communication with any ship or station (or: with.....)?	I am in communication with..... (through.....).
QSP	Shall I inform..... that you are calling him?.....	Inform..... that I am calling him.
QSQ	Is..... calling me?.....	You are being called by.....
QSE	Will you forward the radiogram?.....	I will forward the radiogram.
QST	Have you received the general call?.....	General call to all stations.
QSU	Please call me when you have finished (or: at..... o'clock)?	Will call when I have finished.
*QSV	Is public correspondence being handled?.....	Public correspondence is being handled. Please do not interfere.
QSW	Shall I increase my spark frequency?.....	Increase your spark frequency.
QSX	Shall I decrease my spark frequency?.....	Decrease your spark frequency.
QSY	Shall I send on a wave length of..... meters?	Let us change to the wave length of..... meters.
QSZ	Send each word twice. I have difficulty in receiving you.
QTA	Repeat the last radiogram.

*Public correspondence is any radio work, official or private, handled on commercial wave lengths. When an abbreviation is followed by a mark of Interrogation, it refers to the question indicated for that abbreviation.

In order to pass the government examination, an amateur or expert must be familiar with the signals adopted by the International Radiotelegraphic Convention. This is an important question covering a license of communication.

(Continued from preceding page)

KYW—Westinghouse Electric & Manufacturing Co., Chicago.

Amateurs Still Increasing

The interest in radio has been demonstrated also by the applications for amateur transmitting stations, of which there were 16,467 on September 1, 1922. On June 30, 1921, there were but 10,809 amateurs authorized to send radio communications. Since that time, fifteen months ago, 5,658 more have been added to the ranks using 200 meters wave-length.

The Radio Primer

Weekly A B C of Radio for the Beginner, in which Elementary Facts and Principles Are Fully and Tersely Explained

IF radio waves use the ether of the air, why is the earth necessary?

Electricity must have a positive and a negative pole before it can be made to travel from one point to another. Electric currents always travel from a positive pole to a negative pole. If a radio wave of only one pole—either positive or negative—were to be

Showing the wave length measurement of a continuous wave.

sent to the top of the antenna, there would be no corresponding negative pole to attract it. Therefore, to secure a movement of the waves, the earth must be used as the other pole. The sketch shows how the wave travels. Part of the wave is above the earth's crust, the corresponding half is beneath it.

* * *

What is meant by the wave length?

A radio wave is supposed to have the shape shown in the illustration.

Hoops of the electrostatic component of an electric wave motion.

The length of the wave is figured as being the distance from the top (crest) of one wave to the top of the next wave.

* * *

Now that we know what wave lengths are, what have they to do with the sending and receiving of messages?

One may have his own idea; but the best answer to this question is the recent transatlantic achievement of the Amateur Radio Relay League by which it was proved that a short wave can travel great distances. Wave length does not have a bearing on sending distance, but the latter is not directly dependent on it. The large stations, such as the transatlantic, use the longer wave-lengths because they

By Lynn Brooks

are least affected by atmospheric disturbances and because it would be more difficult and more expensive to generate the high frequencies of short waves while using high power.

* * *

Transmitting stations use a number of wires, while for receiving only one wire is used. Why is this?

The problem at the sending station is to shoot out just as much electrical energy as can possibly be handled. The additional wires provide this capacity. At the receiving station it is not advisable to try and pick up a great amount of the transmitted energy. It is better to arrange an aerial in the most economical manner and then use the energy so as to get the most from it. The receiving station is also bothered with receiving impulses of interference either from other stations or from waves generated in the air by natural means. A multiwire aerial picks up more of both kinds of waves and makes it necessary to lose much of the signal energy in order to get rid of the interfering energy.

* * *

Why is it that radio signals do not continue traveling forever?

If the earth were perfectly flat and without trees, houses, or wires, and if the air did change its character by day and night, there is no reason why the waves should not continue indefinitely. But every tree is a miniature antenna which picks up some of the ethered energy, houses and wires afford an easy path into the earth, and the air is affected by the sun rays to such an extent that much of the initial energy of the waves is neutralized.

* * *

Then would a one-wire aerial be best for receiving purposes only?

This depends on the location and general make-up of the station. If the amateur is located over fifty miles from a broadcasting station, he should not attempt to receive with anything less than an outdoor aerial consisting of one copper or phosphor bronze wire, one hundred or more feet in length. If he is within fifty miles and intends to install an outfit with one or more stages of amplification, then an indoor aerial may be considered.

* * *

Why is one-wire considered sufficient for a receiving station?

For two reasons: wave length and static. Most amateurs are concerned

primarily in the broadcasts which are sent out, with a few exceptions, on 360-meter wave lengths. To receive these broadcasts most efficiently, the natural wave length of an aerial should not be over 360 meters. The second reason has to do with radio's greatest enemy—static. Therefore, the greater the number of wires making up the aerial, the greater the static charge on them. The greater the aerial the stronger the signals received, but not in the same proportion. For these reasons it is best to sacrifice some of the signal strength in order to reduce the intensity of static.

* * *

What is meant by the natural wave length of an aerial?

Every aerial has a wave length which it should pick up without any tuning whatsoever. This is the natural, or fundamental, wave of the aerial in actual use.

* * *

If the frequency of these waves are inaudible, how are they reduced?

After the detector has eliminated one-half of each wave, it has done all in its power—all that may be expected. The remainder of the action must be carried out by the telephone receivers. Every time an operator at the transmitting station presses the telegraph key, a series of little sparks jump a gap and travel to the antenna. To a listener it sounds as if the spark were a single one, but it is really made up of hundreds of little sparks that start without much power and gradually grow to their highest power then decrease to zero again. If we had a pen that could move fast enough it would trace a series of curves. For it is the sparks that leave the gap and pass up the aerial wire and down to the ground connection. In general, the spark impulse can be considered as having the same form until it strikes the receiving antenna, passes down through to the tuning coil, thence to the detector.

* * *

What happens to this wave when it meets the detector?

The detector refuses to pass the entire wave. It will, however, allow one-half to pass through.

* * *

Will these waves make sound in the phones?

No; because they are still traveling too frequently. They must be slowed down many more times before the little diaphragm in the phones will transmit their message to the ear.

The Theory of Radio Communication

How Radio Waves Are Generated so We Are Able to Hear Them

By Horace Beers

THE atmosphere is composed of atoms of oxygen, nitrogen, helium and other gases suspended in what the average individual terms "nothing, or a vacuum." "Nothing," however, is known to radio engineers as ether. Ether can be given a wave motion similar to that which occurs in water.

To transmit radio signals it is necessary, therefore, to first create waves in varying groups and of varying strength; second, to intercept them with apparatus capable of changing them to sound waves.

To create the waves it is necessary to have two surfaces separated by a distance of from ten to several hundred feet and to create between them an electrical pressure which changes its direction—first toward one surface, then toward the other—hundreds of thousands of times every second.

It is the common practice to use the ground for one surface and provide another surface by erecting a structure composed of one or more wires insulated from the earth and suspended many feet above it. Between these, by means of suitable transmitting equipment, we create an electrical pressure of from one to twenty thousand volts, which radiates in all directions.

These pressure waves are, however, only part of a radio wave. From any wire in which the current is flowing electro-magnetic and pressure electro-static waves are radiated.

The creation of these waves may be compared to the action of hurling a rock into a pool of water. The amperes of current put into the antenna correspond to the size of the rock, while the volts of electrical pressure are equivalent to the force with which the rock is hurled. The

larger the rock and the greater the force behind it, the bigger the splash and consequent waves. The more amperes of current flowing in the antenna circuit and the greater the pressure (volts) between antennae and the ground, the stronger the waves radiated. These radio waves have similar characteristics to another class of waves—sound waves. When the note, C, is struck on a piano, the sound waves it produces vibrate 256 times per second, and either a C tuning-fork, or wire, tuned to C—or in its immediate vicinity—will vibrate 256 times also. Then the two wires are said to be in resonance. The waves radiated by a radio transmitter always produce a definite number every second. In order to hear a station, the receiving equipment must be put in resonance with the waves radiated by the transmitter. This operation is known as tuning.

Smallest Two-Stage Amplifier and a Dry-Cell Set

(C. Kadel & Herbert News Photos)

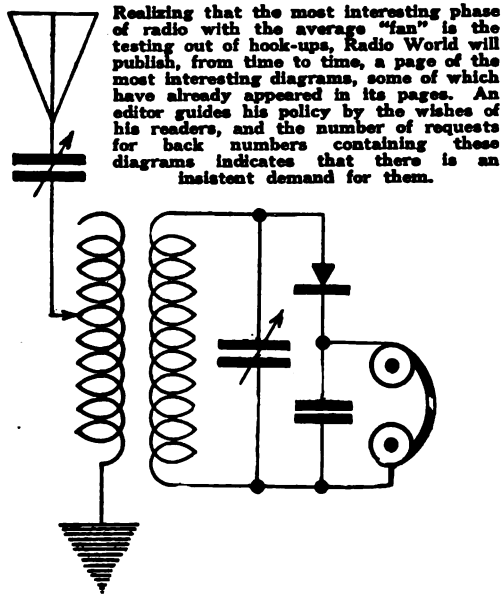

Two new and distinct apparatuses for radio use are shown in the above pictures. They were constructed by William A. Bruno. The first illustration is that of a two-stage amplifier which, Mr. Bruno claims, is the smallest of its type. Due to its small size it is obvious how such a small amplifier could be made to operate. Mr. Bruno, of the American Institute of Electrical Engineers, built this amplifier for the purpose of making it a "space saver." Two vacuum tubes, two transformers, and the rheostats are all confined in the cabinet. One control takes care of both tubes. Notwithstanding its small size it is so well designed that it eliminates all distortion. Another important feature of this amplifier is that it eliminates

(C. Kadel & Herbert News Photos)

the troublesome storage-battery for lighting the filaments and, in its place, uses the dry cell as its filament power. The smaller engraving at the right shows a set which also operates on the dry cell. Without a doubt, more people would own radio sets if the costly and bulky storage-battery could be eliminated. Of course, radio sets using the dry cell would become more popular. Concerts have been received from Detroit and Pittsburgh as well as other local stations, using but one dry cell. This receiver is a compact one of the coupler-type. There are simple circuits with a physical connection between the aerial-ground circuit and the closed circuit, known as the oscillating circuit, in which the detector is placed. Since this work is not concerned with the theories, or mathematics, of radio, but rather with the application of the results, many sets are used with the distinct aerial and ground, also oscillating circuits, with no physical connection between them. Transference of energy between the former and the latter is affected by means of two windings which are brought in to more or less close inductive relation. In one form, these windings are known as the loose coupler; in another, they form a vario-coupler. These coils are in this machine. The vacuum tube is mounted on top of the cabinet. The dry cell is along side to be used as fuel for filament lighting.

Radio World's Page of Hook-ups

Realizing that the most interesting phase of radio with the average "fan" is the testing out of hook-ups, Radio World will publish, from time to time, a page of the most interesting diagrams, some of which have already appeared in its pages. An editor guides his policy by the wishes of his readers, and the number of requests for back numbers containing these diagrams indicates that there is an insistent demand for them.

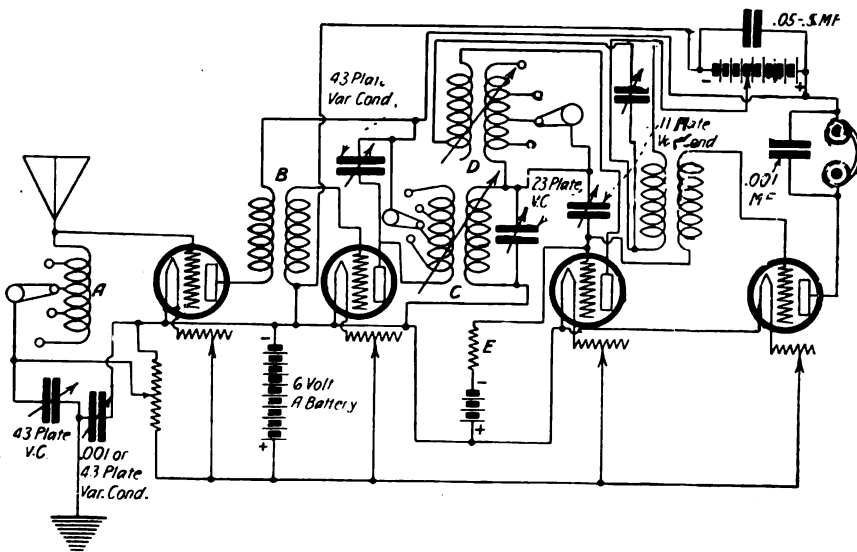

Schematic diagram of a crystal receiver, showing the loose coupler in a circuit. This method of coupling is termed inductive coupling. It has many advantages over the conductive or single circuit receiver. Suggested by Charles H. Plath. Drawn by S. Newman.

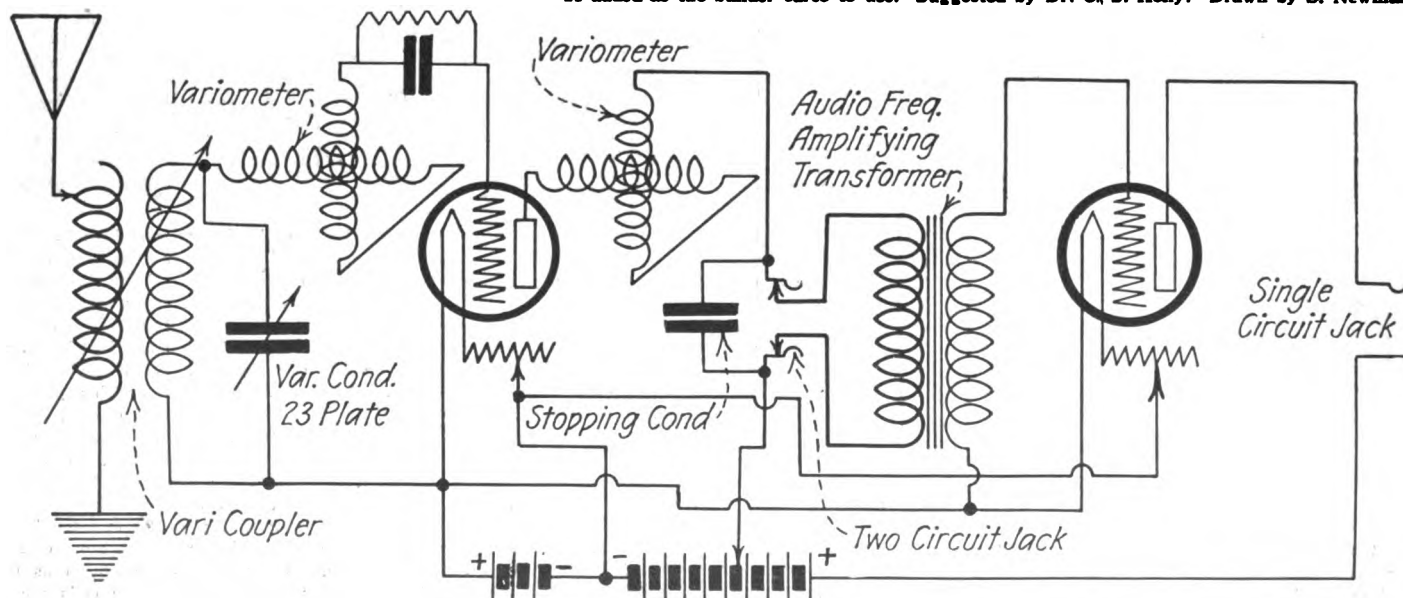

Schematic diagram showing the amplifier and detector with radio-frequency transformer. P is a plug from the tuning circuit, J-1 the jack of the amplifier. Suggested by Harold S. Potter. Drawn by S. Newman.

Schematic diagram of regenerative receiver of the variometer type. In the above hook-up it is easy to discern where the variometers are placed in the grid and plate circuits, respectively. Suggested by George W. May. Drawn by S. Newman.

Schematic diagram showing circuit employing radio-frequency. A is the loading coil. B, any standard radio-frequency transformer. C-D are variocouplers. E is a variable grid leak from 1½ to 3 volt bias. As many stages of radio-frequency and audio-frequency may be added as the builder cares to use. Suggested by Dr. O. S. Kelly. Drawn by S. Newman.

Schematic diagram of a regenerative set, employing variometers as means of regeneration. Jacks are utilized in the stages, which enables the radio listener to use as many stages as he desires. The grid condenser shown in the circuit of the second stage may be left in or out. This is to be considered by experimentation. Suggested by Fred. Chas. Ehlert. Drawn by S. Newman.

Parts of a Radio Receiver

THE telephone receiver commonly employed in radio reception is known as the watch-case receiver.

It consists essentially of a permanent magnet, A, with pole pieces having a north and south pole. On these poles are wound coils consisting of many turns of fine wire, as shown in B.

C is the case of the receiver which is made either of aluminum or bakelite.

E indicates when a current is sent through the coil of the magnet which takes this position.

F indicates when the current flows in the opposite direction, decreasing the total strength and allowing the diaphragm to spring away from the pole.

A D-C resistance of a receiver, as described, would be about 2200 ohms. Over 10,000 turns of fine

Schematic diagram showing the inside of a telephone receiver, and indicating how the telephone functions.

wire are employed to make up the winding. The impedance to an alternating current, of course, will be greater, depending on the frequency of the current and the effective resistance of the circuit. At 400 cycles, a certain receiver of this type had an impedance of 2900 ohms; at 800 cycles, an impedance of 3900 ohms; at 1000 cycles, an impedance of 4400 ohms. This is the type receiver used by most amateurs and radio operators, to-day, in radio reception, whether it be spark, undamped, or telephonic reception.

Army Tank Directed by Radio

ONE of the new Signal Corps radio sets designed for the whippet tanks of the United States Army was tested out last week, for the first time, at the annual field day of the Army Ordnance Association, Aberdeen, Maryland. The standard sets, designed for the master tanks of each group, include both telegraph and telephone apparatus. Under direction of the commanding officer, in the rear, the radio tank executed intricate orders immediately, charging and attacking enemy tanks directed solely from back of the lines. Observers report a most satisfactory test.

Radio Apparatus that Hurls Messages Across the Atlantic

(Both photographs, C. Central News Photo Service)

The huge radio stations used for transatlantic work are interesting studies. One of these stations, the Radio Central, located at Riverhead, Long Island, New York, some seventy-five miles east of the metropolis, contains some of the most valuable radio apparatus in the world. The actual operation of this station takes place in New York City. The operator located there sends the dots and dashes over land wires to Riverhead, from which place they are broadcast. In order that messages of such a nature may be sent, it is imperative that the proper power and circuits be employed. The illustration at the top shows the switchboards which control the power. The various meters and circuit breakers which appear on the front of the switchboard keep the operator informed in regard to the power being used and also the power being transmitted to the aerial. The illustration below shows the transformer rack.

Radiograms

Latest Important News of Radio Garnered from the World Over, and Reduced to Short Wave-Lengths for the Busy Reader.

THE management of the Hotel Belmont-Causarinas, Bermuda, proposes the installation of radiotelephony for the reception of the United States broadcasts. In view of its ideal situation on one of the highest points of the islands, the Hotel Belmont is particularly adapted to the installation of radio apparatus. The stretch of several hundred feet between the hotel proper and the Causarinas Annex provides an excellent span for an antenna.

The boys who attended after school Athletic Centre 62, New York City, received a pleasant surprise from their teachers. As school was dismissed, a large scoreboard was set up in the outer yard, and all the plays of the World Series were bulletined as fast as they were received by radio. About 1,000 boys watched the returns, and expressed delight at getting the scores and plays. The teachers felt that the plan was worth while, as it served to keep the boys out of the traffic-crowded streets where they would have gone for the results.

Formation of a broadcasting company by the six principal manufacturers of radio equipment in Great Britain is announced by Frank Gill, chief engineer of the International Western Electric Company and president-elect of the British Institution of Electrical Engineers. The company will have a capital of \$500,000. Present plans call for the erection of stations at London, Birmingham, Manchester, Newcastle, Cardiff, Glasgow, Plymouth and Aberdeen.

The authorities at Yale University announce that athletic events will be broadcast by radio. This means that anyone within a distance of fifty miles of New Haven, will be able to receive by radio, play-by-play, reports of all the university's athletic events. All that is necessary is a small Crystal radio-receiving outfit.

The Radio Corporation of America has purchased the White Oil Building at 64 to 68 Broad Street, New York City, which it now occupies as its headquarters. The White Oil Realty Company is the present owner of the property. The building is ten stories high and contains 43,000 square feet and is valued at close to \$1,000,000. It is within two blocks of the principal cable and telegraph forwarding offices and is near the Postal Telegraph Company's headquarters. The name of the building will probably be changed to "Radio House."

Southwest Texas is coming to the front in radio affairs, according to the various county fairs held recently. There have been more than a dozen county fairs so far where loud speaking radio apparatus carried music and world news to the rural residents for the first time from WJAE at San Antonio.

Lord Louis Mountbatten, cousin of the Prince of Wales, is visiting New York City with his bride, who was Edwina Ashley, heiress to the great fortune of her uncle, Sir Ernest Cassel, Lord Mountbatten, before the war a Battenberg Prince, is a lieutenant in the British Navy and he told reporters that he intended to specialize in naval radio.

A proposal of marriage by radio is reported by "The American," New York. John Smiley, a wealthy engineer, sent "Will you marry me?" by radio, across the Atlantic, to Miss Evelyn Greeley, moving-picture actress, who is touring Europe. However, it is reported, Miss Greeley will return soon to answer "Yes," in person.

Radio has played a real part in the "movies." Marshall Neilan uses it in his forthcoming picture, "Minnie." In this production, suggested by George Pattulo's story, "Her Man," radio is employed not only as a means of carrying the voice, but also as a medium of conveying power through the air and running distant automobiles, wind-machines, pumps, and other machinery.

The Hippodrome, New York, radio enthusiasts were particularly elated last week when Edward Demmler, master electrician of the playhouse, with a radio receiving set of his own development, was able to hear the attempts being made to relay a telephone message from San Francisco to London.

WJZ, at Newark, has invited the Republican and Democratic candidates for Governor and United States Senator in New York and New Jersey to speak from this station. The follow-

ing tentative schedule has been arranged: Governor, New York—Alfred E. Smith, Democrat, October 25; Governor Nathan L. Miller, Republican, November 1. Governor, New Jersey—Senator William N. Runyon, Republican, October 18; Judge George S. Silzer, Democrat, October 21. Senator, New York—Dr. Royal S. Copeland, Democrat, October 31; Senator William M. Calder, Republican, October 24. Senator, New Jersey—Senator Joseph E. Freylinghuysen, Republican, October 20; Governor Edward I. Edwards, Democrat, October 28.

H. V. Carpenter, dean of the State College of Washington, school of engineering, claims that ordinary telephone wires may be used instead of aerial antenna in radio reception without interruption of either service. Professor Carpenter claims that conversations over the ordinary telephone are not heard on the radio receiving set when telephone wires are used for antennae, nor are radio messages detected on the telephone, so there is no interference or interruption in the service of either. This is probably the biggest step yet taken in the popularizing of radio, for it eliminates the most difficult feature of the receiving station.

A radio-equipped flying boat broadcast news of the National Airplane Races, at Detroit, on October 9. Those who listened in on 507 meters received the first radio report of an aviation meet. A high-powered flying boat, christened the "Wilbur Wright" by Miss Katherine Wright, sister of the "fathers of flying," was equipped by the General Electric Company with a 50-watt radio transmitting set with a range of 100 miles. Reports from this aircraft were sent successfully on a wave length of 507 meters, a length that was not too great for even the small crystal sets to tune with. Soaring at a height of 3,000 feet, this flying boat observed the contestants in the various events and sent reports by radio on the progress of the races. Special receiving sets were placed about the flying field so that spectators were informed constantly regarding the position of the planes, even when they were out of sight.

A novel use of radio broadcasting has been announced by "Adventure." In a series of radio talks, L. Patrick Greene, of the editorial staff, will read the answers to a number of questions submitted by readers to the "Ask Adventure" experts, from WJZ, at Newark, twice a month. Nearly fifty experts having first-hand knowledge of the far corners of the earth have been answering readers by mail, but will now use radio. If "listeners in" wish to know about Alaska, India, Borneo, Central Africa or any other country, they are invited to mail their questions to the editor.

New York City becomes the world's radio central station, and the United States gains great commercial advantage by arrangements concluded by the Radio Corporation of America, which organization has placed under one head American, British, German, French and Argentine radio plants, representing an invested capital of \$170,000,000. Concluding stages of the negotiations, in progress several months, have been arrived at by radio between Edward J. Nally, president of the American corporation, who is in Paris; David Sarnoff, vice-president in New York City; Captain Powhatan Page, vice-president and general manager of the Pan-American Wireless Telegraph and Telephone Company of Buenos Ayres, who came here six weeks ago in furtherance of the plan, and officials of the British and German radio interests.

Chauncey Olcott, comedian, returned so seriously ill on board the "Orbita" of the Royal Mail Steam Packet Line that a radio message was sent to his physician, Dr. John A. Stillwell, of 9 East Forty-ninth street, New York, to meet the ship at the foot of Morton Street. The radio was sent from midocean.

A radio corporation, capitalized at 200,000,000 yen, approximately \$100,000,000, soon will be established in Japan, if plans formulated by the Nippon Yusen Kaisha, the Osaka Shosen Kaisha, the Industrial Bank, Suzuki & Co., Takata & Co., Mitsui & Co., Okura & Co., Fujita & Co., Viscount Shibusawa and other Japanese financiers receive the support of the government and are brought to completion. The plans have been laid before Premier Kato and have received this personal sanction. It is desired to form a company that will compare favorably with the Radio Corporation of America, the Marconi Company of Great Britain, and the Telegraph Company of France. The new company will concern itself principally with improving communication between Japan and America.

Radio and the Woman

By
Crystal D. Tector

ONE of the most attractive numbers sent out by WBZ, Springfield, Massachusetts, is the church service conducted by the Reverend Mrs. Frank L. Briggs. Mrs. Briggs is an ordained minister and served her husband's church as a regular pastor during his absence in France. Her choir is as follows: Hazel Rogers, soprano; Esther Carlson, soprano; Helen Page, alto; Dorris Armstrong, alto; Anna Carlson, accompanist. Truly, women and radio are doing their share to spread religion.

Another unusually interesting broadcast, in which a clever woman was the bright particular star, was the address of Miss Minnie Tracy, a prominent music teacher, who told of her work with the late Enrico Caruso. Miss Tracy was a personal friend of Caruso. Her address was replete with some wonderful reminiscences of the famous tenor.

A woman friend whose hobby is golf has become, also, an ardent radio fan—and all on account of a new golf ball with "a radio-active center." She tried to secure a brand of ball, she says, which she had used for years, and the radio ball she purchased because the dealer was out of her favorite kind. She says that this new ball, when hard hit, races yards farther than any other she has used.

The big alternator in the musical comedy, "Molly Darling," now playing at the Liberty Theatre, New York, really gave me a thrill. It was the first time that I had seen radio on the stage in a truly startling way. The management is wise in saving this piece of dramatic intensity until the last scene, for it is a very unusual climax to a snappy entertaining show.

Miss Jessie E. Koewing, recently gave a very interesting talk on radio before the Men's Club, Belleville, Ohio. Miss Koewing, as most every radio fan knows, is the announcer at WOR, Newark, New Jersey and by the bye, one of the best announcers in the country. After the talk, Miss Koewing was accosted by one of the members who told her that his seventeen-year-old daughter had made a wonderful receiving set entirely by herself. I wish that I might meet and interview this girl. Miss Koewing, in the rush of the night, did not get her name, but I would consider it an honor, indeed, if she would write me and tell me all about it.

WJZ recently broadcast a joint recital by Effie Briggs, soprano; Vincenzo Alpino, tenor, and Hazel Gruppee, pianist and accompanist. Miss Briggs began her musical career when only a child. Her dramatic ability, much in evidence in high-school entertain-

ments, suggested that some day she would develop into a celebrated Shakespearean exponent. She attracted the attention of several Bostonians who suggested that she prepare for a grand opera career. She has studied under Camille Bonsignora and other grand opera coaches. Miss Briggs is quite versatile, being able to sing in nine different languages. "Including radio?" asked Friend Husband when I told him of Miss Briggs's versatility.

They tell me at many of the New York department stores, that the most interested—and frequently, the most numerous—customers at the radio counters are the mothers whose young sons act as escort. Of course, it is the boys who actually want the sets, not the mothers! But it is mother who opens her purse to purchase the set, and, also, to ask innumerable questions in regard to the new magic. A well-informed radio clerk told me that several mothers told him that radio sets have tops and balls and other matters of boyish interest beat to a standstill as a suitable reward when Johnnie has been extra good.

One of my correspondents—a lady who lives in Portland, Oregon—writes to ask if I can tell her what Major Edwin H. Armstrong looks like. I saw the major when he demonstrated his superregenerative set at Columbia University. In fact, I stood very close to him. He is a very interesting personality. Unless you watch them very closely, his blue eyes do not flash. He has an open interesting face, an erect figure, rather prominent mouth, and is beginning to show traces of baldness. But what impressed me most was his modesty. I doubt if I ever met a more modest young man in all my life. Looking into his face, I would say that he becomes wonderfully animated when trying to solve some deep problem.

I have been asked by several women's radio clubs to speak before them this winter. Really this is impossible. In the first place, I am a poor speaker; in the second, I dislike traveling; in the third, I prefer to write what I have to say. I am always pleased to tell my sisters, through the courtesy of RADIO WORLD, anything they may want to know—and may I be so bold as to add that some of my pages in RADIO WORLD this fall and winter, will contain matter that may be read to advantage before any club. You will always find some practical informative paragraphs every week that will be worth saving and that, when put together, will comprise a better lecture than I could deliver from the platform. We women are not good talkers as a rule.

Broadcast Bill's Radiolays

(Copyright, 1922, Westinghouse Electric & Manufacturing Co.)

THEY say the village barber shop's the most convenient place to settle all the troubles that affect the human race. The one we've got in our town's no exception to the rule, so as a natural consequence, the shop is always full. Since Mister Barber first invented tools fer cuttin' hair, the way the government should run has been decided there. The last time I went down to get my curly locks cut short, I helped them settle questions that we thought of great import. But gosh! with nine ahead of me I had to wait so long I said right then the next time I'd amuse the waiting throng in manner more befitting, so to speak, an' up-to-date than tryin' by our talking to direct the affairs of state. An' while I like to keep our land from goin' to the dogs, I'd rather have 'em tell me what's the market price on hogs. So yesterday, when I went in to get my weekl' shave, the barber shop executives had started in to rave about the possibility of war with China soon. I busted up the meetin' when I sez, "Let's have a tune." I'd brought my faithful radiophone along with me this time to listen to while waitin' 'stead of talk of war and crime. With set an' horn connected up, the music came in grand, an' while we

sat there waitin', Sousa's Military Band played four or five selections an' the time went by so fast that pretty soon I noticed I wuz "next!" instead of last. We had some right nice music an' as I wuz gettin' shaved, they told us in the latest news how Wall Street had behaved. "Doc" Dalton runs this barber shop an' I've a dern good hunch, he's goin' to buy a radiophone an' then surprise the bunch.

He asked me all about my set, an' how much I had paid an' if I thought a set like mine would help bring in the trade. Well you know me—I sez, "Why sure, I'd get one right away. Just look at all the extras this here one brought in today."

WJZ to Broadcast Football Games from Field

WJZ, Newark, New Jersey, has, through the courtesy of the Western Union Telegraph Company, arranged to broadcast the more important football games that will be played at the Polo Grounds this fall. The radio audience will not only learn every play the moment it is made, but will also be able to hear the cheering and the songs of the college men.

The schedule is as follows:
October 21—Fordham University vs. Georgetown University, Polo Grounds.
October 28—Syracuse University vs. Pennsylvania State College, Polo Grounds.
November 4—Lafayette College vs. Washington and Jefferson College, Polo Grounds.
November 11—Cornell University vs. Dartmouth College, Polo Grounds.
November 18—Columbia University vs. Dartmouth College, Polo Grounds.
November 25—Army and Navy, Philadelphia.
November 30—University of Pittsburgh vs. Pennsylvania State College, Pittsburgh.

The Most Up-to-Date Things of the

(C. Kael & Herbert News Service)

(Left) A. C. Brown, who, forty years ago, invented the street fire-alarm, has perfected a device which does away with the necessity of wires or even an aerial from the fire-box to the fire station. By means of Mr. Brown's apparatus a high-frequency current is conveyed along the public electric-light mains and collected by a simple apparatus at the fire station, which in its turn sounds the alarm, switches on the fire-station lights, and, what is more, writes on the tap machine the exact place of the fire. The object is for the device to be fitted to all hotels, theaters, and large premises. The call is made by pulling a lever in the usual way.

(Right) The U.S.S. "Langley," the first radio-airplane carrier to be commissioned in the United States Navy. She departed from the Norfolk Navy Yard recently for her first duty at sea. The "Langley" will operate in Chesapeake Bay and vicinity for the purpose of carrying on experimental work in connection with aircraft operations from the landing platform which covers the entire ship.

(C. Underwood & Underwood)

(Below) The only positive, yet the simplest, method of determining the condition of a storage battery, is to obtain the specific gravity of the electrolyte (acid solution). A fully charged cell should read about 1.280. A discharged cell should read about 1.150. The illustration shows how this is determined by means of a hydrometer.

(C. Kadel & Herbert News Service)

(Below) This is the new radio receiving set on board the ocean liner "Tuscania." It "hears" from a distance of 1,200 miles, and is one of the most modern of its kind. The chief operator, David E. Thompson, is photographed at the transmitter.

radio outfit snug in a valise. It will even receive while you are in the subway. And if you are riding in the subway and you hear music when a chap sits down beside you, and plants his feet, you never can tell what is in the valise. This radio can be carried in a valise, and if set to receive, even if it will catch whatever part of the radio program is on. If you'll hear it. It is a six-stage audio-frequency amplifier, a complete sustained receiving apparatus, including loop aerial, a complete sustained receiving apparatus, including loop aerial and loud speaker. It can be operated anywhere. (New York, N. Y.)

(Right) J. D. Freed, radiotrician, designing a radio-frequency receiving set to receive long distances on a loop aerial, and for modest distances without any aerial whatsoever. Mr. Freed (shown in the illustration at the right) claims that he has successfully overcome all the disadvantages of radio frequency circuits.

(C. Kadel & Herbert News Service)

The accompanying illustration shows Rutledge R. Mayo, of the United States Navy, with an Armstrong super-regenerative set which he built himself. By means of a special type vario-coupler, constructed by himself and placed in a certain position in the circuit, he successfully overcame the trouble that is being encountered by amateurs—that is tube noises and that whistle which is sometimes discouraging. In this three-tube circuit Mr. Mayo uses no rheostats or potentiometers. 1, represents the Western Electric loud-speaker; 2, the high-voltage B batteries necessary for the plates of the tubes; 3, the control or condenser dial; 4, the E tubes (Navy type) used throughout the circuit; 5, the vario-coupler. The loop aerial can be seen to the left on the table. Mr. Mayo has received WWJ, Detroit.

Uncle Sam's Foreign Trade Expanding Because of Radio

UNCLE SAM'S "sell-it-by-air" plan, the first practical application of broadcasting to business, is developing rapidly, Department of Commerce officials state. Following the broadcasting from Boston, of the Department's trade opportunities throughout New England, many Chambers of Commerce throughout the country have asked for similar service for their broadcasting stations. Several of the high-powered radio stations have offered their services to the Bureau of Foreign and Domestic Commerce for this new and unique method of making public trade opportunities in foreign lands.

The broadcasting station of "The Times," Ridgewood, L. I., is anxious to serve the territory around New York City. Another station, WFO, Dayton, Ohio, desires to receive information on the world's markets that it may be broadcast to the exporters in the Miami Valley. A station at St. Louis has already begun to broadcast foreign trade notes, and the Chamber of Commerce, Buffalo, wants the data for use in two of its local stations.

It is understood that the Bureau of Foreign and Domestic Commerce, Washington, D. C., is considering sending weekly data to other localities where it will be distributed by radio to interested manufacturers and exporters.

American Industry Best in Two Years

A RECENT business survey issued by the Department of Commerce states that American industry is now marking up the best record for production since the period of depression two years ago. This increased output is general with all industries. Factory employment is larger than since December 31, 1920, which is held to be the chief factor in a more even distribution of buying power.

Service Above Profits

THE business world is going to yield more happiness to those who are engaged in conducting business, when more business men develop the true scientific attitude of mind. Once upon a time an investigator used to try to keep the results of his studies to himself so that he personally might profit by them. Nowadays research specialists give freely to the world whatever they have discovered that is worth while. They have placed service to humanity above personal profit. Some may consider it too idealistic to be carried through in the world of business, but the curious thing is that the business men who are practising this high idealism are making greater profits than they ever could by using a more selfish system.—Tom Dreier, in "Forbes Magazine."

Measuring Shadows

Time was when men climbed the pyramids with great effort and sweating (for it is hellish hot in Egypt) and then after all this effort, often inaccurately, measured their height.

One day an old, lame man with a large staff hobbled out on the desert, stuck his support in the sand and measured its shadow. Then he measured the shadow of the pyramids and knew exactly their height.

Some men measure the value of advertising by the loss of much money, sweat and toil. They pick out the oldest radio publication, or the one that claims the largest circulation, or the one that jams the largest number of advertisements together, while all the advertiser is really seeking in spending his good money is to get consumer results: Orders, cash returns.

Let us tell you how to simply measure the value of your radio advertising dollar by the shadow method; that is, the result your competitor is getting from his advertising in RADIO WORLD—the results others have had from keyed advertisements where the same copy has been tested in each of the radio publications.

This shadow measurement will give you an accurate measurement in advance of just the kind of results you may expect from RADIO WORLD. We KNOW and you can know it is the best buy in the radio advertising field.

Heard at the Radio Counter

A Conversation Between Customer and Radio Clerk

"I WOULD like to know the difference between a regenerative receiver and a non-regenerative?"

"Well—you see, with the regenerative receiver, the plate circuit is broken and a coil, known as a tickler, is inserted in series with the plate and telephone circuit. This is not in the non-regenerative."

"Then, please tell me, what is its advantage?"
"It makes possible the reception of C-W, or continuous waves, which cannot be received on the plain nonregenerative set. It also amplifies the signal immensely."

"Well, I have a vario-coupler of the nonregenerative set, and would like to make mine regenerative. What must I do? What do I need?"

"You need a vario-meter placed in the plate circuit. This will do the trick. You also need another vario-meter in the grid circuit. This will make your set regenerative."

"Will this work also with the crystal-type receiver?"

"No. This will only work with the vacuum tube."

"Well, if I use a vario-meter, what will the wave lengths be?"

"The wave lengths of this vario-meter receiver should range between two hundred and six hundred meters."

"Let me see. I guess I'll take the vario-meter and try it out."

"All right—sir. Let me know the results."

Capital Increases

Radio Craft Co., Brooklyn, \$10,000 to \$800,000.
Home Radio Corporation, \$10,000 to \$35,000.

Coming Events

The editors of RADIO WORLD will gladly publish news items of all contemplated radio shows and exhibitions. Keep us posted by mailing full information.

CHICAGO RADIO SHOW, Coliseum, Chicago, Ill., October 4 to 22. U. J. Hermann, managing director, 549 McCormick Building.

SECOND NATIONAL RADIO EXPOSITION, direction International Trade Exposition Co., Chicago, January 13 to 20, inclusive, 1923, George A. King, director of publicity, 417 South Dearborn Street, Chicago, Ill.

PERMANENT RADIO FAIR FOR BUYERS, Hotel Imperial, New York City. Open from September, 1922, to May, 1923.

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, December 21 to 31, Company, Fisk Building, New York, N. Y.

TRI-STATE TOBACCO GROWERS' RADIO SHOW, Covington, Ohio, October 21 to 23, inclusive.

INTERNATIONAL RADIO SHOW, Madison Square Garden, New York City, November 20 to 25, inclusive. E. C. Buchignani, director of publicity.

SOUTHEASTERN RADIO EXPOSITION, Auditorium Armory, Atlanta, Georgia, December 4 to 9, inclusive.

Jump in Radio Sales

ALFRED FANTL, financial writer for "The Tribune," New York, one of the close observers of commercial conditions in the United States, published the following in his department last week:

A sudden and large jump in radio sales occurred during the week, when many department stores sold as much in a single day as they had previously disposed of in the course of one week. The impetus, while in part due to fall revival of interest in radio, owes much of its suddenness to the enterprise of the press in reporting the world series via the air—a demonstration of radio's practical utility which could have no more susceptible portion of the public for the making of an impression at once instant and profound.

New Circuit for Experimenters

The above schematic diagram is a hook-up of a single-coil receiver. It is the work of Mr. W. Miller, Southern Methodist University, Dallas, Texas. The amateur who delights in experimenting should give this circuit a trial. A duo-lateral coil, No. 56, is inserted between the aerial and the ground. The grid condenser and leak are connected in the circuit of the coil and ground. The plate circuit is brought to one side of the aerial and, also, to one side of the telephone jack. Careful adjustment of the set is necessary. Radio World requests all amateurs experimenting with this circuit to make a report to its Technical Editor as to its receiving qualities as well as to the distance secured.

Facts You Should Remember About "Litzen Draht"

THE advantage of *litzen draht*, a wire made in Germany, for winding inductances with a very low resistance and having a large surface, is recognized. This wire is composed of a number of enameled copper magnet wires separately insulated from one another, and braided, the whole covered by a single-braided silk wrapper. *Litzen draht* is employed in research laboratories and particularly where high efficiency is required.

The following describes the number of wires, the size, and the number of feet per pound. These facts are of vast importance to every amateur.

4 Wires, No. 28 B&S (Brown & Sharpe gauge), made up in 4 strands of 6 wires each, enameled, with silk wrap. The strands are cabled around a hemp core and the whole covered with 2 wraps of green or white silk, 3835 C.M. (circular mill), No. 14 B&S; approximately 90 ft. to the pound.

30 Wires, No. 36 B&S, made up in 3 strands of 10 wires each, cabled and served with 2 wraps of silk, 750 C.M., No. 21 B&S; approximately 332 ft. to the pound.

90 Wires, No. 38 B&S, made up in 10 strands (3x3), enameled, with one wrap of white silk, 1415 C.M., No. 19 B&S; approximately 225 ft. to the pound.

48 Wires, No. 38 B&S, made up in 6 strands of 8 wires each, enameled, cabled with 2 wraps of natural, black or green silk, 775 C.M., No. 21 B&S; approximately 415 ft. to the pound.

48 Wires, No. 38 B&S, made up in 8 strands of 6 wires each, enameled, with 2 wraps of natural, black or green silk, 775 C.M., No. 21 B&S; approximately 415 ft. to the pound.

10 Wires, No. 38 B&S, enameled, stranded, with one wrap of silk 155 C.M., No. 28 B&S; approximately 1600 ft. to the pound.

20 Wires, No. 38 B&S, enameled, strand-

ed, with one wrap of silk, 310 C.M., No. 24 B&S; approximately 800 ft. to the pound.

120 Wires, No. 40 B&S, made up of 3 strands of 40 wires each, enameled, with 2 wraps of black silk over all, 1200 C.M., No. 19 B&S; approximately 250 ft. to the pound.

32 Wires, No. 38 B&S, 4 strands of 8 wires each, enameled, with 2 wraps of black silk, 500 C.M., No. 21 B&S; approximately 605 ft. to the pound.

48 Wires, No. 38 B&S, made up in 3 strands of 16 wires each, enameled, with 2 wraps of natural silk, approximately 400 ft. to the pound.

10 Wires, No. 40 B&S, stranded with 2 wraps of colored silk, 99 C.M., No. 30 B&S; approximately 3000 ft. to the pound.

162 Wires, No. 38 B&S, made up in 18 strands of 9 wires each, enameled, cabled, with 2 wraps of green or white silk, 2250 C.M., No. 16 B&S; approximately 125 ft. to the pound.

36 Wires, No. 38 B&S, made up in 6 strands of 6 wires each, enameled, cabled and served with 2 wraps of green or white silk, 566 C.M., No. 22 B&S; approximately 500 ft. to the pound.

Cleaning Files

MANY amateurs experience trouble when they attempt to use a file on some of the softer metals, such as lead, aluminum, copper, says "The Mail" New York. This is due to the metallic particles clogging the teeth of the file, thus rendering them ineffective in cutting the metal. In some cases the metal particles clinging to the file will scratch the object being filed, making a rough surface. This difficulty can be overcome by rubbing the surface of the file with ordinary stick chalk, such as is used for writing. The presence of the chalk on the surface of the file and in the crevices between the teeth is to prevent the filings from sticking and filling up the cutting surface. This same result can be obtained by dipping the file into hot water.

For best results equip your Magnavox Radio with

Magnavox Power Amplifier

THIS apparatus has been placed on the market in response to many requests for a power amplifier giving distortionless amplification of music and voice, previous amplifiers having been developed for signals only—where distortion does not show.

To accomplish the desired purpose, the Magnavox Power Amplifier had to be especially designed, and internal circuits, grid potentials and amplifying transformers are entirely different from those in other amplifiers. Any of the standard tubes can be used.

The use of the Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Radio. Switching from stage to stage is made easy by master switches, as illustrated.

Brushed bakelite panel, mahogany case, without tubes or high voltage batteries.

3-stage, AC-3-C, Price...\$110.00

2-stage, AC-2-C, Price... 80.00

The Magnavox Power Amplifier, Model C, was designed for use especially with the Magnavox Radio, and is made with the same insistence upon high quality and efficient service.

Magnavox products can be had of good dealers everywhere.

Every Member of a Radio Set Is an Auxiliary Policeman

IT is announced that arrangements have been made to equip the metropolitan police force with a comprehensive radio outfit. This is the happening of the expected—not to say the inevitable, says Henry Smith Williams, in "The American," New York. Radio has such obvious possibilities as a police agency that its use in this field must become universal.

Already important beginnings have been made. Out in Chicago, for example, the police department has been using radio-equipped automobiles for some time. Patrol wagons have been equipped, experimentally, with wireless outfits that keep them in touch with headquarters at all times. It is reported that perfect communication has been established, the tests being satisfactory in every way.

When a crime or disorder is reported to headquarters by ordinary telephone, word can at once be flashed by radio in every direction and a universal alarm given in a fraction of the time previously required. The entire police force might thus be on the lookout for a criminal attempting to escape in an automobile, and the probability of interception of the fugitive enhanced enormously.

An obvious difficulty that suggests itself is that the ether may be vibrant with other messages. Broadcasting stations, for example, are busy at almost all hours of the day, to say nothing of commercial and amateur stations.

The difficulty is to be met in New York—and doubtless the same expedient will be adopted elsewhere—by allotting to the police department a special wave length that is not to be used by any other radio station in the vicinity.

The wave selected for the metropolitan district is 400 meters. It remains to be seen whether messages on this wave-length will interfere with the 360-meter wave used in general broadcasting. If it does, a larger wave, perhaps 500 meters, will be employed.

With radio-receiving telephones of the newer type, equipped with loose-couplers and condensers for accurate tuning, there should be no difficulty in shutting out the police messages, or vice versa. But less elaborate sets, not being able to tune sharply, may mix up concert and lecture with reports of robberies and murders in distracting fashion. But at worst this will serve as an incentive to the radio fan to improve his apparatus.

Meantime, every owner of a receiving radio set becomes potentially a member of an auxiliary police force.

Radiofacts

Transmitting sets are essentially the same as receiving sets with the exception that they must have a source of power, and of course the apparatus must be so designed that it will carry this power.

The microphone is the most important electrical mechanism in the transmitting studio. It plays a part similar to the transmitter of the ordinary telephone by picking up sound waves, causing the diaphragm to vibrate and create corresponding changes in the current flowing through the circuit.

The capacity of a storage battery is governed very largely by the quantity and quality of lead and oxide of lead used in its construction.

Two things must happen to the radio frequency currents before they get to the phones. 1st—They must be allowed to move the diaphragm of the telephone. 2nd—They must move it at audible frequencies—below, say 4,000 cycles per second which is the top note on a piano.

Reliable and Beautiful
RADIO-A
RE-CHARGER

THE RADIO-A is a highly efficient dependable piece of apparatus, absolutely fool-proof, easily attached by simply plugging into ordinary 110 volt lamp socket. In case of current failure, the unit cuts out automatically until current is resumed, without discharging battery.

It is designed expressly for re-charging radio filament batteries, but may be used for automobile or any other storage battery of reasonable size and capacity.

Price, \$18.50

Dealers and Distributors

Here's a Winner! Write us for full particulars.

Simply screw into any 110 volt lamp socket and connect the terminals to your battery. Impossible to hook-up wrong—RADIO-A charges either way.

A compact portable Re-charging Unit that will fully charge a 100 A. H. Battery overnight, for from 5c to 10c, according to prevailing rates.

are broadcast. The stations listed by the Navy League to date are: The four Westinghouse stations, Springfield, WBZ; Newark, WJZ; Chicago, KYW; and Pittsburgh, KDKA; General Electric, Schenectady, WGY; Detroit Free Press, WCX; Southern Radio Corp., Charlotte, WDT; Richmond-Crosby, Memphis, WKN; St. Louis Post Dispatch, KSD; Tulano Univ., New Orleans, WAAC; The Times Union, Jacksonville, WDAL; Reynolds, Denver, KLZ; Spokane "Chronicle," KOE; "Desert News," Salt Lake, KZN; Kansas City "Star," WDAF; Atlanta "Journal," WSB; Dallas "News," WFAA; Oakland "Tribune," KLX; Great Falls "Tribune," KDYS; Honolulu "Star-Bulletin," KDYX.

Listening-In Association Formed

A DECIDED increase in popular interest toward radio is promised. The larger broadcasting stations have installed more elaborate transmitting apparatus and equipment; all stations have profited by their experiences the past few months. Listeners-in will increase in number. All listeners-in—dependent as they are on the nature and variety of broadcasts for their entertainment, and on the quality of the receiving apparatus used—would desire naturally a medium for the exchange of their views and comments.

The National Radio Listeners-in Association of America is an organization formed in Washington without capital and with no commercial interest. Its object is to encourage cooperation between operators of broadcasting stations and the greatly increasing numbers of listeners-in included in the term "general public."

The bi-monthly meetings have satisfactorily affected changes in such matters as increased range, improved modulation and details of performance pertaining to individual artists appearing on programs.

First results noted locally, encourage the members of the association to suggest similar action in other communities, welcoming any request for assistance and seeking helpful suggestion.

Comment or suggestion in the interest of the public and radio are cordially invited.

The officers of the new association are: L. C. Hedges, president; James W. Cook, vice president; O. J. Hodge, chairman, board of critics; M. D. Meyerson, chairman of publicity; H. W. Ennes, corresponding secretary; William A. Eaton, treasurer.

Address: 901 Varnum Street, N. W., Washington, D. C.

Twenty-One Stations to Broadcast Navy Numbers

IN co-operation with the Navy League, 21 broadcasting stations will include special Navy numbers in their programs on Navy Day, Friday, October 27. At some stations, speakers will narrate on the history and the prowess of our Navy; at others, Navy musicians and vocalists will render musical selections, while a few will broadcast programs now kept secret in order to surprise the listening radio enthusiasts. The only government station on the list is the well-known NOF, at Anacostia, where most of the governmental programs, including the famous Marine and the Washington Navy Yard Band Concerts

Radio Patents

Schematic diagram showing a modification of the ground antenna of the Hanson-Jones invention, with means for varying its capacity constant.

Underground Antenna

No. 1,429,240. Patented, September 19, 1922. Patentees: Earl C. Hanson, Washington, D. C., and Edward F. Jones, New Orleans, La.

THE object of this invention is to provide an underground, or subterraneous, antenna-system applicable for installation within a limited area; also, to provide for varying the consonants of the antennae by directly modifying the capacity of the antenna collectors.

Experiments have determined that under-the-earth antenna construction, such as Mr. Hanson has devised, possesses feature of distinct advantage over underground systems heretofore employed. The concentrated capacity-area gives the same effective antenna-surface as long, buried single-wire conductors, and gives substantially the same signal energy as the long, buried conductors. It has been found that placing the capacity antenna areas a distance of, approximately, fifty feet apart, radio signals have been received from considerable distance and at high audibility.

Radio waves progressing in the earth's crust will induce a charge on the antenna capacity-areas due to the electrostatic component of the radio wave

and the antenna circuit will oscillate due to the phase relation of the charges impinging upon the capacity areas. Under certain conditions, satisfactory results are obtained by using smaller antenna capacity-areas and, therefore, the variable antenna capacity-system may be utilized for a wide range of wave lengths. Where stations are required for operation on predetermined wave lengths definite capacity areas may be employed. However, where it is necessary for stations to communicate with numbers of stations operating at various wave lengths the means may be used to change the effective area of the capacity to obtain syntony with the cooperating station.

In the practical operation of the Hanson system, it may be found advantageous to have the antenna capacities placed directly beneath the station and allow the rotating handles of the variable antenna-capacities to project through the floor so as to enable the operator to readily control the capacity values for various wave-lengths. The system is not limited to operation over only a small band of wave lengths, but is applicable for long-wave operation such as is employed by high-power oceanic stations.

ing stage. The invention, in many of its aspects, is equally applicable to the amplification of signals in any order of frequency.

A further object of the invention is to increase the amplification to telephone currents, or to carrier currents, over that obtainable by the usual vacuum-tube amplifying circuits, by the use of feedback circuits.

In general, the invention consists in the modulation of an alternating current, of a frequency, say, of 1,000 cycles per second or higher, by the incoming signal impulses, the amplification of the modulated alternating current and the demodulation of the amplified current.

* * *

To Prevent Loss of Energy

No. 1,429,453. Patented, September 19, 1922. Patentees: Harold J. Power, Somerville, Mass.

HAROLD J. POWER, vice-president of the American Radio and Research Corporation, Medford Hillside, Massachusetts, has been granted letters patent on an inductance device which should prove useful in that important phase of radio. In certain electrical current carrying instrumentalities, of

Figure 1 is a top plan view of an inductance device arranged in accordance with my invention, and Figure 2 is an enlarged vertical section on the line 2-16 of Figure 1. At 10 and 11 are shown inner and outer supporting members of any suitable insulating material.

which inductance devices furnish an example,—and especially those employed in connection with such high-frequency currents as are present in wireless or radio installations—it is important to prevent the loss of energy from the conductors through their insulating supports, and to so compactly arrange the devices that little space is occupied and, further, so that two or more of the devices may be brought into close relation to produce a mutual effect.

Low-Frequency Amplifier

No. 1,428,154. Patented, September 5, 1922. Patentees: Lloyd Espenschied, Hollis, N. Y.

THIS invention relates to the amplification of low-frequency signals, such, for example, as ocean cable, telegraph signals or those emanating from the propeller or engine noises in submarine detection. Such signals have a large, or predominating, direct current or very low-frequency component which is not transmitted or inefficiently transmitted through the ordinary repeating coils used in the local circuits of thermionic amplifiers. An object of the present invention is to provide an arrangement for amplifying signals of this character which will amplify all low frequencies, including the direct current, without the necessity of a metallic connection between the successive stages of the amplifier and without the

attendant difficulty of preventing the output battery of one stage from affecting the input circuit of the succeed-

Schematic diagram of Mr. Espenschied's low-frequency amplifier.

Radio Will Write History

ACCORDING to Mr. Lloyd Jacquet, A writing in the "Evening Mail," New York, history will be written during the three weeks from December 12 to 31, by the members of the American Radio Relay League, when the second attempt will be made to "speak" across the Atlantic Ocean. During that period, writes Mr. Jacquet, we "shall probably see amateur radio assuming international proportions."

A series of preliminary tests for the purpose of determining what American and Canadian transmitters shall be given a place in the final tests with an individual schedule and code letters, will be conducted from October 25 to November 3, inclusive. To qualify for the final tests a transmitter must cover a distance of at least 1,200 air line miles during the preliminary tests.

The preliminary tests will cover a period of two and one-half hours (9.30 p. m. to midnight, central standard time) which is divided into ten periods of fifteen minutes each. Transmission will take place by inspection districts. One district transmits at a time, and all others remain silent endeavoring to copy as many of the transmitting stations as possible. After the tests each night, the receiving stations are to send a confirming record to all transmitters heard at a distance of 1,200 air line miles or over.

When filing application for entry in the final tests, a transmitter shall include at least one 1,200-mile record, or show documentary evidence that its signals have reached out 1,200 air line miles during the months of September or October.

The amateurs who succeeded in being heard in Ardrossan, Scotland, where the official listening post was installed, constitute a memorable and historical list. They were:

Spark stations—1 AAW (not yet located). 1 ARY, Burlington, Mass. 1 BDT, Atlantic, Mass. 2 BK and 2 DN, Yonkers, N. Y. 2 EL, Freeport, L. I. 3 FB, Atlantic City, N. J. 8 BU, Cleveland, O. 9 ZJ, Indianapolis, Ind. 3 BP, Newmarket Ontario.

United by Radio

A remarkable incident was credited to radio when two old army pals were united and an old debt "paid in full," through WGI, the high-powered broadcasting station of the American Radio and Research Corporation, Medford Hillside, Massachusetts—adds one more laurel to her long list.

When Professor Connor, of Emerson College, Boston, gave a reading by radio from WGI, last week, he was not aware that among his audience was a man he had been seeking for over three years, a pal of his army days. They had parted at the Army Hospital, Staten Island, New York, and had gone their separate ways without an opportunity to strike hands in parting. Neither had heard of the other until Sergeant Kepple, listening in at Wilkensburg, Pennsylvania, to the radio program from WGI, heard the voice of his army chum with the result that the following night-letter was received by Mr. Connor the next morning:

Professor Joseph E. Connor, Mansfield, Massachusetts.

Been trying to locate you since discharged from Army. Last night heard your radio readings. Am sending postal order amount one hundred dollars paying your kind loan at Army Hospital, Staten Island. Many thanks, old son-of-a-gun. Didn't know you were professor. Would have borrowed two hundred. Your erstwhile sergeant,

KEPPLE.

Professor Connor says he is going to use the hundred dollars for expenses to Wilkensburg to visit Sergeant Kepple.

Creed System to Speed Up Code

RADIO code-communications from ships and land stations, which radiophone users frequently hear as they tune in the broadcasting concerts, are transmitted by hand, generally at a speed ranging from twenty to thirty words a minute, says "The Times," New York. Since the early days of wireless various methods of automatically recording messages at high speed have been developed in order to facilitate the clearing of heavy traffic in the shortest time possible, especially between long distant points. The high-powered trans-Atlantic transmitters and receivers are in constant operation, day and night, handling the hundreds of radiograms and press reports between Europe and the United States. To use a speed of thirty or even forty words a minute would require many hours to get the latest press news and business messages across the sea. One of the latest methods of speeding up radio communication is know Creed system, which is applicable at the present time for commercial work at a speed of 180- words a minute.

One of the greatest problems in the operation of printing or recording radio apparatus is the necessity of accuracy of the signal form; that is, the duration of the dots and dashes. The accuracy required for mechanical or automatic receiving must be carried to a much higher degree than if the reception is through a headset and the human ear, and more particularly so when high telegraphic speeds are used. For the operation of the high-speed mechanism it is necessary to insert a mechanical relay between the valve circuits. A relay in this case is an instrument actuated by the radio currents after they are amplified to sufficient strength to cause the relay to operate and control other instruments in the circuit. The new relay used in connection with the Creed system was developed in England and has features which overcome many of the difficulties and deficiencies existing in mechanical relays. Its salient points are: stability of adjustment, firmness of contact, pressure and absence of rebound, sensitivity, shortness of transit time and ability to work at high speeds.

In connection with the Creed system the signals are transmitted in the ordinary continental Morse code. The impulses are picked up by the antenna, wires are passed through special vacuum tube amplifiers which build up the signal strength sufficiently to actuate the relay, capable of following the dots and dashes perfectly up to 200 words a minute with a current as low as one-quarter milliampere. The relay in turn operates a perforator which punches the dots and dashes on a paper tape. This tape is run through an automatic typewriter which records the messages in print on another tape. The new features of this relay are ability to follow at high speed and at the same time work with entire fidelity on such a feeble current. The inertia of all the mechanical parts as well as the electrical magnetic circuits have been so finely calculated that the maximum efficiency, theoretically possible, is produced.

That Armstrong Circuit

So much interest has been displayed in the special article "TESTED INVENTION OF MAJOR ARMSTRONG AMPLIFIERS SET 100,000 TIMES," by John Kent, that appeared in RADIO WORLD No. 13, dated June 24, 1923, the publisher decided to put aside a number of copies for those who were not able to get this issue when published. Copies will be sent, postpaid, on receipt of 15c. or send in your subscription, \$6.00, for one year (52 issues) \$3.00 six months, or \$1.50 three months, and subscription will be started with the issue containing the article about Major Armstrong's Amplifier.—RADIO WORLD, 1498 Broadway, New York.

The "Why" of the Farmer's Happy Life

FER years an' years th' most serious drawback t' farmin', next t' th' hard work an' element o' chance, has been that it isolates a feller an' keeps him out o' touch with th' affairs o' th' world.

Fer many years most farmers had t' manage t' git along fer weeks an' months without hearin' from th' outside world.

It wuz hard fer 'em t' remember who th' president o' th' United States wuz, an' they didn't know whether ther friends an' relatives wuz dead or alive unless a letter or newspaper wormed thro', or by chance they got t' town.

Then come th' telephone an' rural free delivery, an' th' farmer wuz fairly able t' keep a line on his relatives, European affairs, and th' price o' eggs.

Then th' automobile bobbed up an' is a big factor t' day in bringin' th' farmer's relatives t' his very door, an' also in whizzin' him an' his family t' town for a band concert or a hall show.

But drivin' t' town ever' night, or havin' th' home full o' relatives soon gits t' be a chestnut, an' besides it eventually runs into money.

We believe that next t' th' harvestin' machine an' a pump in th' kitchen th' best an' so fer th' cheapest thing that's happened fer th' farmer in many a day is th' invention o' th' radio 'phone.

The' radiophone's performances already have proclaimed th' end o' isolation. Th' farmer no longer has t' drive t' town, or entertain a house full o' hungry relatives, or depend on a day-old newspaper fer his news o' th' outside world.

Th' seas an' lakes an' continents, burnin' deserts, frozen wastes, an' mountain peaks, have all been over passed.

Th' farmer an' his family may now know when a car is stolen from in front o' th' courthouse, or when a schoolhouse is burnin' up, or when a treaty is signed, as soon as th' ether waves kin deliver th' news t' ther vocal loud, or speech amplifier.

After a hard day o' toil th' farmer, without even changin' his collar, or rollin' down his sleeves, kin tune in an' take his pick out o' ever' thing in th' air.

An' all about him sits his family t' hear what's goin' on in th' world in th' way o' news, singin', music, an' oratory.

If they tire o' th' 'Wabash Blues,' they kin tune in a lecture on onion culture, or th' treatment o' hog cholera, by some expert in Detroit.

Maybe he kin pick up a saxophone solo from Hurley, Wisconsin, or a bagpipe sextette from fer-away Scotland.

Maybe his congressman is sendin' out words o' cheer, or there is a fire in town.

It's no uncommon thing t' jest innocently tune in on a fine helpful sermon from Pittsburgh, or Wheelin', an' it's no trouble t' tune off o' it.

But ther's no longer any excuse fer folks that are imprisoned on remote farms t' git behind on th' affairs o' th' world—not t' be able t' whistle th' latest airs, t' know when th' President misses a chance to play golf, t' keep track o' th' bonus bill, an' all th' latest gossip about prosperity.—Abe Martin in "Farm Life."

Experienced Stage-Fright When Broadcasting

WHEN the red light is turned on you'll know 'you've got the air,' said Herbert S. Houston, publisher of Our World, on his return to New York from a trip West, to the Advertising Club News. "This was the signal," he went on to say, "for my first experience in broadcasting an address. It was in the big radio station of the St. Louis 'Post-Dispatch' and I was broadcasting an address on 'What Europe Means to the Mississippi Valley.' I think I can truly say that the only time I was ever

seized with stage-fright was this particular time when I wasn't on the stage—but instead, talking through a microphone to a vast invisible audience.

"A few minutes after I concluded my address a telephone bell rang and an attendant said that I was wanted on the phone, much to my surprise. George Burbach, the advertising manager of 'Post-Dispatch,' had called in from many miles out in the country to say that he had just heard my radio address and that he heard every word distinctly and perfectly. It all seemed most marvellous—even in this age of marvels—that one could broadcast an address by radio and then be called on the long-distance telephone to be informed that the address had carried across."

Answers to Readers

I have a three-coil regenerative set. May both variable condensers in this set have 43 plates? Is there any difference in the primary

condenser if placed in the aerial, circuit instead of the ground lead? Will a plate battery having variations of 1½ volts give sharper tuning?—Joseph Lamkin, Minneapolis.

The variable condenser in the aerial circuit works best with a 43-plate variable condenser which is .001 mfd., capacity. The other variable condenser is of the 23-plate type with a capacity of .0005 mfd. It makes no difference whether the 43-plate variable condenser is placed in the ground or aerial circuit; both function the same. A variable plate-battery may increase the signal strength, but it will not give sharper tuning.

I notice in all schematic diagrams that the secondary circuit is connected to the negative side of the A battery. Diagrams that I have received from the De Forest company connect the side to the positive pole. Which is correct? I also note that the phones are connected to the positive side of the B battery. Can you explain this?—Paul Keller, Springfield, Mass.

It makes very little difference with which side of the A battery you connect the secondary circuit, but it seems to function best on the negative side. It makes no difference which side of the B battery the phones are connected in.

I have a home-made crystal set, an 80-foot aerial, and 2,000-ohm receivers. Sometimes I can hear the concerts clearly; but, at other times, nothing is audible excepting code. Is my circuit O. K.? Can you suggest any changes?—Russell Williams, Jacksonville, Fla.

Your set is not connected in the most efficient manner. Connect one end of the coil-winding to the ground lead, and, also to one end of the phone condenser. Connect the other side of the phone condenser to one side of your detector, and the other side of the detector to one side of the slides on the tuning coil. The other side of the tuning coil goes to the aerial lead. This circuit will prove more satisfactory. Of course the telephones must be connected across the phone condenser to make things audible.

Where can I buy "peanut tubes?" Can they be used in a regenerative set, using spider-web coils? What causes the regeneration in a plate variometer since there is no inductive relationship with the secondary of the vario-coupler as with honey-comb coils?—James Cudahy, Williamsport, Pa.

"Peanut tubes" may be used in any place where any detector-tube may be used. In the variometer type of a regenerative set, re-

Spirola Concert

TRADE MARK PATENT PENDING

THE COMPLETE LOUD SPEAKER

—No "units," headsets, extra batteries or adjustments required. Complete with cord, ready to connect in, in place of your headset.

LOUDNESS—Just a sample of actual performance. In our testing laboratory, using a small outdoor aerial and an ordinary set with two stages of amplification (the ideal set for average conditions unless near a broadcasting station) we have received broadcasting stations more than six hundred miles away, so loud it can be heard a hundred feet away. Or again, while this compact little instrument (it stands less than eight inches high) is designed for home use rather than for large halls—yet with the same set stations thirty miles away come in somewhat louder by direct comparison than a full sized phonograph playing a loud record with a loud steel needle.

And **TONE**—While we welcome comparison on loudness, what will really impress you most about your SPIROLA CONCERT is the tone. We have absolutely eliminated distortion and all metallic, "tinny" quality. Violin, orchestra music, voice, even the difficult piano come to you through your SPIROLA so clear and natural you can hardly believe they are not in the same room.

Beautiful cabinet type, choice of dark oak or mahogany finish, bronzed throat; at your dealers or prepaid anywhere in the U. S., Canada or England **\$12.50**

We are so sure you will be pleased with your SPIROLA CONCERT that we absolutely guarantee it. If you wish to return your SPIROLA for any reason whatsoever, do so within ten days and your money will be immediately refunded. Made and sold by

REPRESENTATIVES WANTED!

RADIO WORLD wants young hustling subscription representatives in every college, school, factory and big business concern throughout the country. Send us your name and address for full particulars. RADIO WORLD, 1493 Broadway, New York City.

generation does not depend on an inductive relationship but does depend on simply tuning the plate circuit to exact resonance with the grid circuit. When the two circuits are in resonance, the high-frequency resistance is greatly lowered with the results that much more energy is allowed to circulate.

Who is WCG, 2 AKH, 2RM? What is the meaning of QTA?—Samuel Lebowitz, New York City.

WCG is the Bush Terminal station, 36th Street and Second Avenue, Brooklyn, New York; AKH is the station of D. Hopkins, 450 East Fourth Street, Brooklyn, New York; 2 RM is the station of F. A. Mayer, 828 55th Street, Brooklyn, New York. QTA means, "Kindly repeat your message."

Would four wires, 25 feet long, amount to the same and give the same results as one 100-foot aerial?—Bob Moore, Brooklyn, New York.

Using four 25-foot wires will not give you the same results as a hundred-foot aerial in one stretch. Change from the 25-foot aerial. Erect the hundred-foot aerial in one length.

I would like to see a diagram of a single-slide tuning coil showing the connection and slider.—Harold Kent, Kingston, New York.

Diagram of single-slide tuning coil requested by Harold Kent, Kingston, N. Y.

The above diagram shows a single-slide tuning coil with a slide rod and two connections. This is used in conjunction with the crystal detector.

On what schedule and wave does the Anacostia station operate?—Harry Leavy, Hillside, New York.

The Anacostia radiophone station, Anacostia, D. C., operates on two schedules a week, Wednesday and Friday. Both schedules are transmitted on 412 meters commencing at 8.30 p. m. Eastern standard time and ending about 10 p. m.

I am enclosing a circuit to which I would like to add two stages of radio frequency and two stages of audio frequency now in use. Please furnish wiring diagram as mentioned, recommending the transformers to be used. This is a wonderful circuit, and, I believe, second to none. As a detector, I have heard voices from stations a thousand miles distant.—W. Miller, Dallas, Texas.

Applying radio frequency would mean that a complete change of equipment and wiring would have to be done. Why employ radio frequency when you can hear the distance you mention? Probably radio frequency will not give you this range. Stick to what you have and do not bother with radio frequency at present.

To receive continuous waves, do I need the rectifier—crystal or vacuum-tube? Should it be audible in the phone receiver without rectifying the wave received? If not, why?—Frank Paseta, Buffalo.

You cannot receive continuous waves with a crystal detector unless you have an external heterodyne-system in order to make the received signals audible in the telephone. It cannot be done with a vacuum tube unless you use a regenerative receiver with a vernier control, so the receiver may be turned into a self-heterodyne. Heterodyne in this case means, simply, a local source of power

production which will create waves of radio-frequency either just below or just above the frequency of the incoming wave. The two waves will then clash or, in other words, be out of phase with each other 500 times every second. This will produce an audible note, corresponding with the dots and dashes in your telephone receivers, of a frequency of 500 cycles per second.

Universal Phone Connector

Can be used with any type receiver. Makes possible the use of four sets of phones. Eliminates energy loss. Heavily nickel-plated, and guaranteed to give complete satisfaction.

ATTRACTIVE PROPOSITION FOR JOBBERS AND DEALERS.

**MICROSTAT
VERNIER RHEOSTAT**

The most sensitive filament control and quickest, easiest tuned. This microstat has ten times the possibility of exact filament adjustment as over the ordinary wire rheostat.

It eliminates grating and interfering noises, has single knob adjustment and is far more durable being made of better material with greater care.

This microstat takes up less room on the radio board, is neat and compact. The exact calibrations of the microstat are due to the gradual entering of two points into the resistance material of our own composition which gives us exacting and most minute measurement of current to the filament as the operator brings the two points together or separates them through the screw handle.

Order through your dealer or delivered to any part of U. S. **\$1.40**

Every One On His Own Wave Length

WITH the advent of cooler weather, which is to bring with it tremendous demands for radio broadcasting, there is arising a certain amount of bitter feeling against the amateur who either is transmitting code or testing his home-made broadcasting station, says "The World," New York. In the larger cities these amateurs are becoming so numerous, and are in many cases so disregarding the government regulations regarding wave lengths, that they rapidly are becoming hindrances to the thousands of persons who desire to listen to the programs being broadcasted by the larger and more efficient stations. Now there is no getting away from the fact that the amateurs have as much right to operate as have the broadcasting stations; they have as much right to fulfil their desires for pleasure as have the owners of receiving sets, and have as much right to improve their work as have the more powerful plants. But it must be remembered by them that there are government regulations forbidding them operating on other than certain wave lengths and that when they violate these regulations the chances are they are infringing upon the pleasures of their neighbors. No one believes any of the amateurs who are preventing others enjoying concerts are doing so intentionally, and it has been proven that a call on the air or on the wire phone will result in the amateur either returning to his correct wave or standing by until after the close of the program with which he is interfering.

Identifying Mark for WGY

THOSE who have listened in recently on the programs of WGY, the General Electric Company's radio-broadcasting station at Schenectady, New York, have observed a whistle between numbers. Some fans have thought the whistle was due to an imperfection in their receiving outfits; others, observing that the whistle came only from WGY, were convinced that there was something wrong with the transmitting outfit. Neither theory is right.

The whistle, or musical note, is caused by an audio-frequency oscillator used at the transmitting source for the convenience of the audience. The oscillator comes into play by means of a relay which is operated when the studio switch is thrown off. The instant a musical number is ended in the studio, the whistle starts.

This musical note, or whistle, will become characteristic of WGY—an identifying mark, if the audiences approve. If listeners in dislike the device, it will be discontinued. Many people have reported that they have lost the station between numbers, and before tuning in again the next number is well underway and they have failed to get the announcement. There is sometimes a slight delay between selections, a delay which seems minutes to the man at the receiving set though it is actually only seconds. He thinks he is out of tune and begins to retune. The musical note persisting during the intermission enables him to know whether he is still in tune with the station.

Any single copy of Radio World, beginning with No. 1, mailed on receipt of 15 cents postpaid. Any seven issues for \$1.00. Or send \$3.00 for 6 months (26 numbers) or \$8.00 for 1 year (52 numbers) and have your subscription start from No. 1. Radio World, 1493 Broadway, New York.

IMPORTANT NOTICE:

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Fans Crowd to Hear Talk on Superregeneration

IN all of the annals of amateur radio clubs, the most crowded meeting ever held by any of these clubs came off last Monday night at the meeting of the Radio Association of Greater New York, says "The Globe," New York. At this particular meeting, R. W. Tait gave a highly interesting talk and demonstration of his super-regenerative set. The meeting place was full to overflowing and it is understood that a hundred or more people were turned away.

It is generally recognized that the broadcast listener is sadly in need of education, and the only way that this can be accomplished is through the radio clubs. The Radio Association of Greater New York has set the pace in this matter for the New York district and will, from time to time, arrange other talks of equal interest to every one who has a radio set.

The club in particular is affiliated with the American Radio Relay League and is also connected with the Second District Executive Radio Council. It has been in existence for several years and has a very large membership. This club is probably the only one that has a real dyed-in-the-wool lady operator for a secretary. This young lady, Miss Marguerite M. Powers, has, we understand, a commercial license and is the proud owner and operator of a C. W. transmitter, call letters 2BVX.

If you are interested in radio you should investigate this live organization with the object of becoming a member. The dues are almost nothing, and a club set will undoubtedly be installed in the near future, all of the necessary apparatus having been donated, but no suitable place for installation has as yet been secured. The Radio Association of Greater New York numbers among its members some of the best known radio men and amateurs in New York City, and the beginner will probably be able to secure a valuable radio education by joining the club. Meetings are held every Monday night on the top floor of the public library at 535 West 179th street.

DO YOU USE A CRYSTAL DETECTOR? ARE YOU MAKING A CRYSTAL RECEIVER? Increase the efficiency of your crystal detector 1,000 per cent by using a "PT" Ultra-Sensitive Contact. Of special gauge and alloy; makes and holds a quick, ultra-sensitive, stable, adjustment. Endorsed by RADIO WORLD. Using galena, you may pound panel or table without disturbing sensitivity in slightest. Proved practical on shipboard by an oldtime Marconi operator. Using a "PT" Contact on galena, Arlington (NAA) was brought in clear at 3,300 miles (below the Equator); and Arlington came in loud at 2,200 miles (of Dutch Guiana). In both instances, nearby ships using vacuum tubes were unable even to hear NAA. As to stability, Cape May (WCY) was worked over 1,000 sending right through crystal with 2 KW spark, without affecting detector's adjustment. Replace your insensitive unstable spring or catwhisker with a Contact which will hold its adjustment in addition to giving louder signals and music. Indispensable for use in your crystal set, regardless of make. A novice can install. "PT" ULTRA-SENSITIVE DETECTOR CONTACT, with instructions, twenty-five cents, coin or M. O. "PT" CRYSTAL CONTACT CO., Box 1641, Boston & Massachusetts.

FRENCH TUBES, genuine (no bootleg with French name), most sensitive and economic. (Good for detectors, amplifiers, and especially for radio frequency. Will work very good on two dry cells.) Price \$3.90. ATLANTIC & PACIFIC RADIO CO., 131 W. 37th St., near Bway., New Yrk.

Will Trains Be Controlled by Radio?

ALTHOUGH it does not come directly under the matter of train control, radio train dispatching really comes under this classification, writes Raymond Francis Yates in "The Evening Mail," New York. As early as 1910, Earl Hanson, who is a very-well known radio inventor, was employed by the Santa Fe Railroad to perfect a system of this nature. Hanson rigged up aerials on the cabs of a number of locomotives, and the engineers were communicated with en route. Although very encouraging results were obtained, the railroad officials are hard to please and the experiments were abandoned. With our modern radiophone equipment it would seem that there shouldn't be much of a problem to radio train-dispatching at the present time. The engineer at all times could be within listening distance.

Numerous attempts have been made to establish direct telephonic communication with engineers, but the systems used were impractical. If there is one great need that radio can fill, this would seem to be the one. If the engineer in the wreck had been given a warning message in time he could have brought his train to a stop, and a great disaster would have been avoided. Of course, if the man had fallen dead, and no one knows whether he did or not, all the speaking radio in the world would be of no avail. On an occasion like this, radio control would be the only thing that could be resorted to.

In New York's subways there is a wonderful example of automatic control by a wire system. No more than one train is allowed in a block at a time. If the motorman of a second train passes a block signal, the emergency brakes are applied instantly and without effort on his part. While this system works beautifully in the subway, where the more delicate parts are not brought in direct contact with varying weather conditions, it would not hold up and perform the same services on an outside track.

—and now
harmony replaces discord!

MUSIC—clear as a bell; speech—so that every word is marvelously distinct; jazz—in uninterrupted syncopation; opera—with that transcending, full-toned quality which brings its remarkable beauty into strong relief.

This sort of radio reception *is* a matter of *batteries*. Elimination of most *noises* is a matter of batteries, rather than static or other interference.

These noises are caused by the *irregular* voltage output, natural in ordinary "B" batteries. Where the current output becomes unvarying, these noises cease—and this marvelously clear and life-like reception results.

And it is because RADIOBATS "A" and "B" are the only batteries which act as radio batteries *should*, that we urge you to listen to a demonstration at your dealer's.

Until you have actually heard reception through RADIOBATS "A" and "B" you cannot imagine how wonderful radio *can* be—and there *is* no way to hear it, till these epoch-making, new-principle batteries are hooked in.

RADIOBATS "B"—as well as "A"—are *leak-proof* because they have the only *solid electrolyte*; and they are more economical, because, like "A" Batteries, they are indefinitely *rechargeable at home*.

Send now for the intensely instructive booklet "The permanent Power Unit for Radio" and send your dealer's name and address so that we may arrange an immediate demonstration. There is absolutely no obligation.

Army Antenna Erected in 90 Seconds!

(C. International News-Reel)

The recent reorganization plans of the National Guard of New York provide for the latest in radio equipment. The above is an illustration of the type of low-visibility antenna used by the Signal Corps, Headquarters Company, 71st Infantry. The set is three feet high and can be erected in ninety seconds. This low antenna is specially adapted to the radio work of a battalion in a forward position.

New Wonder of Warfare! Tanks Directed by Hidden Radio Operator

(Both photographs C. Pacific & Atlantic Photos, Inc.)

THERE is no end of romance in the story of the radiophone. It is an invention that came back, so to speak, in a big way after an ignominious career. But such a wonderful thing as speaking and receiving through space, without wires, tubes, cables or other physical connections, was almost certain to fall into the hands of unscrupulous promoters, long before the serious, honest experimenters had an opportunity of evolving something more than a crude, laboratory demonstration. So we find that, a dozen years ago, the radiophone was nothing more than a crude device, making use of a sputtering, uncertain electric arc as a "generator" of the high-frequency machine. The high-frequency, so uncertain as to be almost hopeless, was modulated or varied by means of some form of carbon microphones. This instrument, as anyone familiar with its construction knows, is quite unsuited to the handling of heavy currents.

A series of experiments were being conducted for the United States Signal Corps with a view to proving the practicability of radiotelephony in military communication. After numerous attempts the vacuum tube came into play. It opened a new era in telephone work. The vacuum tube is nothing short of an electrical acrobat. It can do all sorts of tricks—tricks no other electrical device has been able to perform.

Today the vacuum tube is producing most remarkable results, and the latest achievement in the United States Army is the equipment of steel clad "tanks" by radio. With radio it is possible to direct war tanks in the direction they should go! The photograph at the left is the interior of a tank, showing the operator with his radio gear. The lower picture is that of a number of tanks being directed by radio to operate in certain war areas.

A Simple Superregenerative Receiver

By Harold S. Potter

How the front panel will look when completed. The dials should appear on the panel in this manner. The two dials to the right are the rheostats for the tubes; the three large dials are the tuning devices. Drawn by Harold S. Potter.

SUPERREGENERATION is the carrying on of the familiar phenomena of regeneration, beyond the point where it usually must cease, due to the circuit starting to oscillate, making the signals mushy and unintelligible.

When the new system was first placed before the public, great claims were made for it, many of which have since proved unfounded. It was not, as was then claimed, the equal of the seven-tube superheterodyne, for long-distance, short-wave reception. However, for short-wave reception over moderate distances, it is the thing. It is the solution of the apartment-house dweller's troubles, as it makes possible the reception of broadcast entertainments on a small-loop antenna without any outside connections whatever. Formerly this could only be accomplished by the use of a considerable number of tubes, which meant a considerable outlay, but now it may be accomplished with but two tubes.

Superregenerative sets have been built using one, two and three tubes. The one which I am about to describe is of the two-tube type and best for general use.

Many amateurs are under the impression that the superregenerative system is an expensive one to use. This is incorrect, as may be seen by the following list of parts and their cost:

1 bakelite panel 7x18x3/16 inch..	\$3.00
1 wood base 9x18x3/8 inch.....	.50
1 43-plate variable condenser....	4.50
1 23-plate variable condenser....	3.75
2 tube sockets	2.00
2 rheostats	2.00
1 D. L. 1500 coil (unmounted)...	2.75
1 D. L. 1250 coil (unmounted)...	2.25
1 3 1/2 inch rotor.....	.50
1 length cord tubing.....	.10
3 3-inch dials	3.00
1 1-inch radius panel switch.....	.50
12 binding posts60
1 phone condenser30
Wire, brass, screws, etc.....	.50
Total	\$26.25

The panel may be of bakelite,

formica, celeron or hard rubber; but hard rubber is not to be recommended, as it is apt to warp. It may be purchased cut to size and squared up. The dimensions are 7 x 18 x 3-16 inches.

Figure 2 shows the details of the panel layout. If any other make of instrument is mounted on the panel in the place of those listed, allowance must be made for their different dimensions. The holes should first be located by the use of square and ruler, then spotted with a center punch.

The panel should be given a coarse-grain finish by rubbing lengthwise with a piece of No. 2 emery cloth until all shine is removed. A small quantity of olive oil should then be rubbed into the panel. A rich gloss finish will result.

Closely allied to the panel is the base, which is of 3/8-inch hardwood, 9 x 18 inches. Three screws pass through countersunk holes at the bottom of the panel, into the front edge of this base, holding them firmly together at right angles to one another. This base is used for mounting the duo-lateral coils, the tube bases, the battery-connection strip and the tickler bearing.

Two variable condensers are mounted near the center of the panel.

Referring to Figure 3, C is a .0005 mfd. condenser used across the inductance to tune the input. See Figure 5.

C₂ is a .001 mfd. condenser used across the D-L. 1,500 coil. It should be shunted by a .001 fixed condenser, giving an effective capacity of .002 mfd.

The input tuning inductance and the

View of the front panel, showing all necessary dimensions for the construction of this superreceiver. Careful attention should be given to each section. Suggested by Harold S. Potter. Drawn by S. Newman.

Looking into the receiver. This is the "layout" of the equipment, not the position of the various instruments such as the condensers, rheostats, vario-coupler and honeycomb coils. It carries its complete dimensions. Drawn by Harold S. Potter,

(Continued from preceding page.)
 tickler are mounted together in the form of a vario-coupler, the tuning inductance being the fixed member. The form for this inductance is a piece of cardboard tubing 4 inches in diameter and 4 inches long. Starting $\frac{1}{2}$ an inch from the top end, wind for 2 inches with No. 24 D.C.C. magnet-wire, tapping every $\frac{1}{2}$ inch, giving 5 tap leads in all, including the start and finish. These taps are connected to the points of the tap switch, shown in Figure 1, below and between the coupler and condenser dials.

A hole is drilled through one side of this tube, $\frac{1}{4}$ inch down from the top, and another $3\frac{3}{8}$ inches below it, to match the two holes in the panel, and are used for mounting. Two $\frac{3}{4}$ inch 6/32 flat-head nickel-plated machine screws serve to support the inductance. A couple of battery terminal nuts slipped over the screws serve to keep the inductance $\frac{1}{4}$ of an inch from the panel.

The tickler is made by winding a $3\frac{1}{2}$ inch rotor ball with a single layer of No. 28 S.C.C. magnet wire, giving about 96 turns in all.

A $\frac{1}{4}$ inch brass shaft passes through this ball and is supported by a brass angle bracket at one end, while a $\frac{1}{4}$ inch hole in the panel, shown in Figure 2, serves as the other bearing. Great care should be taken in mounting and making the brass angle support to get the hole to line up properly with the

bearing hole in the panel, as otherwise the dial will not run true.

In making connections to this tickler winding use flexible leads in order to allow the ball to run smoothly.

In the variation frequency-generator circuit 2 large honeycomb coils are used. One is a D.-L. 1500 coil, in the grid circuit. This is shunted by the variable condenser previously mentioned. It is mounted back of the tube bases, as shown at L3, Figure 3.

A D.-L. 1250 coil, L4, is connected in the plate circuit, Figure 5.

In Figure 3 is shown the correct relative positions for these inductances, 3 inches apart at their nearest points, and at an angle of 60 degrees to one another. This I found to be the best position in my set, and slightly different coupling may work best on another set; but once they are placed the inductances need not be moved. Figure 4 shows the details of the coil mountings. The brass support is made of strip brass $\frac{1}{2}$ inch wide and $1\frac{1}{16}$ inch thick. The dimensions are shown in the detail drawing. A hardwood plug should be fitted to the center of each coil. But one screw is used to fasten each support to the base, so the angle of the coils may be changed, if need be, by simply loosening this screw.

A most important part of any tube set is the rheostat. The tubes in my set are mounted at the lower right-hand end of the panel, below the peepholes.

Just back of the rheostat are the

tube sockets. These are all bakelite. It is well to remember, when picking a tube socket, to get one which holds the tube snugly and has strong contact-springs, in order that a good contact with the prongs on the tube may be assured.

A mica phone condenser having a capacity of .0025 mfd. is shunted across the phone binding posts at the lower right-hand corner. It may be seen in Figure 3 (C₂). It is supported in place by the wires which connect to it.

At the right-hand end of the base, Figure 3, is a strip of bakelite $\frac{1}{2}$ inch by $6\frac{1}{2}$ inches by $\frac{3}{16}$ inch thick. On this connection panel 8 small binding-posts are mounted, to make connection to the A, B, and C batteries. These posts are placed $\frac{3}{4}$ inch apart. Two $\frac{3}{4}$ -inch roundhead brass wood screws secure the connection panel to the base, while two battery terminal nuts slipped over the screws between the panel and the base keep it raised $\frac{1}{4}$ inch above the base, making room for connecting to the binding posts.

Regarding the dials, any 3-inch 180-degree dial having a $\frac{1}{4}$ -inch shaft-hole may be used. When buying dials be sure to pick ones which are flat and true if even, smooth-running of controls is desired. Also, be sure to get bakelite dials—not those made from molded "mud" composition,

(Continued on following page.)

which have a habit of chipping and splitting.

The handiest binding post to use is the type having a hole drilled through for the wire or phone tip and a set screw. For the sake of appearance, get a small nickel-plated post, not a clumsy brass one.

Only the antenna, ground, and phone posts are on the panel. All battery connections are made to the

well to enclose the set in a cabinet. If you are not handy with tools this should be purchased ready-made.

For those who care to build their own the following particulars are given. The inside dimensions of the cabinet are: 7 inches high, 18 inches long, and 9 3/16 inches deep. Quarter-inch oak, mahogany, or some other hard wood may be used and finished in any manner desired. The top of

cept under-almost perfect atmospheric conditions. However, interfering noises may be eliminated by using a loop antenna. I use a loop 3 feet square, wound with 10 turns of No. 18 bare copper wire spaced 1/2 an inch apart.

Fine results may be obtained on a loop as small as 1 foot square; in fact, little difference in signal strength will be noticed when changing antennae. About 50 feet of annunciator wire may be wound into a loose coil and dumped on the floor, the ends connected to the set. Surprisingly good results will be obtained.

It is almost impossible to give instructions for the operation of this receiver. Adjustment of L2 and of C2 cuts out the howling and whistling which is common to this circuit when out of adjustment. The various stations are tuned in by varying C1 and the tap switch. The final adjustments are then made with the rheostats and with C2.

The above hints will prove helpful, but the builder must learn the meaning of the many indescribable sounds characteristic of this circuit. A little practice will mean more than pages of instructions.

In conclusion, this offers a great field for experiment to the dabbler in superregeneration, as the circuits yet developed have their limitations and there is much improvement to be hoped for in the reception of spark signals over long distances by this system.

And now, you "bugs" who try this set or are experimenting with superregeneration: How about a line or two telling of your results? I would be glad to hear from anyone on this subject.

Claims Receiving Record

If Any Radioist Can Beat Mr. Merklein's or Would Like His Hook-up, Write Him.

Editor, RADIO WORLD: Speaking of receiving broadcasting a la D X, I believe I hold the record. On the night of October 16, at 11:15, I happened to tune out WJZ, and tuned in WDAF. Later I received WSB. Station WDAF is located in Chicago; WSB in Atlanta, Ga.

The concerts came in very clear, and only on one tube. My outfit is of the two-variometer type, and the design of wiring is my own: Two Steps of Audio, frequency—VV 201—detector; VTI—first step; VT2—second step; 110 volts on amplifiers; 4 wire "L" type aerial, 40 feet long and 50 feet high.—Best 73, J. A. Merklein, 7513 Third Ave., Brooklyn, N. Y.

Perfection at Last

Madge: "Do you know anything about this radio fad?"

Marjorie: "It must be just lovely, dear. I understand that you can listen in."

—"The Sun," New York.

Fifty-two issues for \$6.00. Sub. Department, Radio World, 1493 Broadway, N. Y. C.—Adv.

The honeycomb or duo-lateral coils. This diagram shows how they should be mounted. Note the position of their layout. Dimensions are given to assemble them. Drawn by Harold S. Potter.

Schematic diagram of the internal wiring of the complete set. When wiring, it is best to solder all connections that can be soldered. Follow each connection closely as you go along. Remember, one wrong connection will make the set inoperative. When finished examine the wiring. Drawn by Harold S. Potter.

connection panel back of the main panel.

Next comes the wiring. The neatest thing for this purpose is square, tinned-copper wire. If this is not available, No. 14 bare copper wire may be used. In order to make a neat job bend and fit each connection before putting it in place. Make all connections short and avoid long parallel wires, as these tend to produce howling and cause energy losses. Solder all connections.

Be sure to follow the wiring diagram in Figure 5 carefully, as all connections must be correct if results are to be obtained. Carelessness may mean a couple of burnt-out tubes, so it is better to be certain than sorry.

In order to protect the instrument from dust, dirt, and injury, it will be

the cabinet should be hinged to allow for easy inserting and removing of the tubes, and for changing connections. The battery wires should be led in through holes in the side of the cabinet.

A 6-volt, 80 to 100 ampere-hour storage battery will be needed to light the filaments.

For the plate battery, several B-battery blocks of 22 1/2 or 45 volts should be connected in series to give the proper voltage.

The grid, or C batteries, consist of several flashlight cells in series. The necessary voltage may vary from 5 to 25 volts, depending on the tube used and on the plate voltage. I found that 10 volts worked best on my set.

A super-regenerative set cannot be used on a regular outdoor antenna ex-

Takes Radio Circles by Storm

National Radio Week Acclaimed by All

Radio World's Proposition, That Seven Days Be Given Up to Boosting Radio, Strikes Ten with the Trade, Fans, and Amateurs

LAST week's issue of RADIO WORLD (No. 36, October 21) had no sooner reached the newsstands and subscribers than the editors realized that it had landed as a bombshell in radio circles. Telephone calls, messages, and letters soon made it apparent that RADIO WORLD'S announcement that November 26 to December 2 be set aside as a National Radio Week—to create greater public interest in radio, to increase the output of manufacturers, to increase sales by distributors and dealers, to create a wider interest among fans—is about the biggest thing that has hit the radio game since it was started.

It so happened that a luncheon in the interests of radio was held at the Bankers Club, New York, the day preceding this announcement. This luncheon was attended by Hon. Frank H. Hitchcock, J. H. Beyers, H. Gernsback, Laurence A. Nixon, and other men interested in radio promotion. When RADIO WORLD'S proposition was announced, it was so generally regarded as a matter of vital importance to every person and firm interested in radio, that the editor of RADIO WORLD immediately agreed to permit his suggestion to become a general plan of the radio world at large and to permit a committee to decide on the best and most advantageous time for the celebration of National Radio Week.

Consequently, a second meeting will be held Tuesday, October 24 (this page is going into type on October 18), when the proposition will be discussed at length and the final date decided on.

The full report of this meeting will be published in the next issue of RADIO WORLD.

The first letter to be received by RADIO WORLD commending its plan was from Edward M. Morgan, postmaster of New York City. His and other letters follow:

* * *

Laurence A. Nixon, managing editor, says "The Radio Dealer" says it's "smashing good!"

A smashing good idea! It will create a greater interest in radio, boom business, and bring new enthusiasts into our fold.

* * *

Edward M. Morgan, postmaster of New York City, an ardent Co-operator:

As to the proposition that there be a National Radio Week, there is no doubt in my mind but it would be most useful; for it would unquestionably promote the science and industry of radio; and whatever does this will be for the welfare of the nation, since every advance that facilitates the communication of information and intelligence makes for enlightenment and progress. It would have a special utility to the post office at the time suggested, November 26 to December 2, since

it would permit the broadcasting of messages urging early Christmas mailing.

* * *

H. Gernsback, editor, "Radio News," one of the first to commend the idea, writes:

Allow the writer to compliment you on the idea of a National Radio Week. This is a splendid idea, and if enough publicity matter can be broadcast so that the public will become aware that there is such a movement, we are certain that it can only help the entire radio industry.

Personally, the writer thinks that the last week in December would, perhaps, be most appropriate, because it has been found, in past years, that there is more interest in Radio displayed just before and after Christmas than during any other time of the year.

* * *

Kendall Banning, editor, "Popular Radio," is with us:

I am glad of the opportunity not only of endorsing but of actively participating in any movement that will help to establish the radio industry in the high position which it must eventually attain. Your suggestion for a National Radio Week is a step in that direction, and I shall be glad to do what I can to make it a success.

* * *

Paul V. Godley, famous radio engineer of the Adams Morgan Company, New Jersey, says: it will result in good:

I see no reason why such an arrangement as a National Radio Week should not result in some good being done. I must confess at this time, however, that no ideas of value occur to me in connection with your plan, although I shall watch its effect with interest.

* * *

What have YOU to say or suggest? What can YOU do to boost National Radio week in your town? What plan can YOU devise for some novel form of radio entertainment or display. Can YOU get up a radio party that will be pleasant and profitable and introduce strangers to radio?

Suggestions forwarded to RADIO WORLD on this important event will be welcome and will be afforded space in our editorial columns.

But—don't miss next week's RADIO WORLD. (Dated November 4, on sale November 1.) It will contain the very latest and most important news regarding National Radio Week.

Be a National Radio Week Booster

Latest Important Radio News of the Week

THE success of a sixteen-hour test of electron tubes in place of large alternators in transmitting wireless telegraph messages across the Atlantic from the Radio Corporation plant at Rocky Point, L. I., has led Dr. E. F. W. Alexanderson, chief engineer of the corporation, and inventor of the alternators which will soon be supplanted by the tubes, to predict that the transmission of power from Niagara to New York through the air by means of tubes was a possibility of the future.

It is reported that the Prince of Wales has become an ardent radioist and has induced his father, King George V, to install a set in St. James Palace.

Receipt of wireless messages inside a steel car of a fast-moving train with no outside aerial was successfully demonstrated by the Pennsylvania Railroad on the Broadway Limited, from New York to Chicago. The tests were conducted by

Arno Zillger, of Philadelphia. The aerial used was an inside loop device, small and compact, and placed on a table. It was 18 inches square. The radio set was assembled after the train left New York, enroute to Chicago, and immediately was tuned into WOR, Newark. The entire concert was heard during the run to Philadelphia, where a second one was picked up. Broadcasting, even from the Great Lakes, was picked up all the way to Chicago.

A charge that the Radio Corporation of America, the General Electric Company and others have entered a conspiracy to obtain a monopoly of wireless service and prevent individual use of the radio is made in a suit filed in the United States District Court today by John O. Yelzer, Jr., of Omaha, Nebraska, who asks an injunction to restrain the defendants from interfering with his right to broadcast. He alleges that his own radio station was closed recently because he was operating slightly above the 360-meter wave

length, and that the first amendment to the Constitution, which says: "Congress shall make no law abridging the freedom of speech or of the press," is being thereby violated. A jury to determine damages, which he alleges to be \$25,000, is requested, with treble damages under the Sherman anti-trust law and an attorney's fee of \$25,000.

* * *

The Knoxville, Tennessee, automobile club, in conjunction with the other clubs of the state, will broadcast nightly the number and description of all stolen automobiles.

* * *

Chicago newspapers report that half the audience of the recent Radio Show in that city was composed of boys and young men, and that the most interested attendance was at the booth of the National Radio Chamber of Commerce, where experts gave the youngsters advice as to what was wrong with their instruments.

Radio Legislation Slated for December

By *Washington R. Service*

CONGRESSMAN WHITE, of Maine, "father" of the Radio Bill calculated to improve radio in this country commercially, in broadcasting, and for amateurs, has returned to the Capitol and believes that the bill will be taken up by his committee early in December.

The enactment of this long-looked-for legislation will benefit all branches of radio, but officials of the Department of Commerce say that it will not entirely eliminate interference in broadcasting. There are some features in connection with radio which cannot be corrected by legislation, it is pointed out by experts of the government, such as the mastering of one's own set.

Good Sets Badly Tuned

Even if there were enough waves to give each station an exclusive band—and there are not nearly enough—interference would still be encountered, or at least reported, by fans endeavoring to receive the news and entertainment offered by 522 stations, many of them in one community. This would be so because many receiving sets are not capable of fine adjustment and cannot be properly tuned to a specified wave length.

Though possessing excellent sets, many enthusiasts are not able to tune properly; they do not know how to manipulate their sets and eliminate interference within a prescribed band. Already reports have been received by the Department of Commerce that broadcasting on the new 400-meter wave is interfering with that on the 360-wave, which should not be the case with 40 meters between.

If transmission is good, first-class receiving sets should be capable of tuning within a variation of from 5 to 10 meters, inspectors say, unless one station broadcasting is in the immediate vicinity of the receiver.

Although Secretary Hoover will probably receive authority in the radio bill to limit the number of transmitting stations, it will be difficult to accomplish this in congested areas where several broadcasting stations are already located. Municipal authorities and organizations of listeners-in may have to aid the Secretary, when the time comes, by indicating which stations are the best and what services are most desired. The listeners-in are organized in Washington and such a body might become a censor of the air, so to speak, endorsing satisfactory stations and reporting those which are

unsatisfactory, thus aiding in establishing better service. In any event, it is hoped that both wave lengths and time schedules will aid the broadcasting in congested districts.

Must Learn How to Receive

Distributors of radio equipment capable of fine adjustment should instruct purchasers carefully and, when possible, assist them in setting up their sets and tuning in. It is evident that a large percentage of those interested in radio must be educated in the use of their sets, and this may develop on the broadcasters who are interested in having their programs clearly heard or on radio associations. The Bureau of Standards has been giving information along this line for some time.

It is expected by Department of Commerce experts that the loop receiver, possessing directional qualities, will aid in the selection of broadcasts and help in eliminating the other stations' programs, when used in conjunction with tube receiving sets. The cost is not excessive in comparison to an aerial, and as the indoor coil can be installed in a corner of a room, the disfiguring overhead aerial may eventually disappear from housetops. It is part of the question of experimentation and education in radio.

How Radio Is Supplementing the Ticker in Wall Street

THE amplifier is responsible for many radio achievements. For instance, the recent "spanning" of the Atlantic using 1 kilowatt of power, or less, would have been impossible had it not been for the highly efficient receiving equipment and amplifier employed. An ordinary set would not respond to such signals, and the transmitters, under such circumstances, would be incapable of forcing sound over so great a distance. Yet with the proper receiving set and super amplifier the signals from such a weak station were found to span the intervening space with a marked degree of success. This serves to prove that no matter how weak a transmitter may be, its waves are driven through space and kept going farther and farther—endlessly.

The advantage of employing a radio-frequency amplifier is this: It amplifies only the wave and not the many little irregularities and imperfections which exist in the usual receiver and amplifier equipments. No matter how many steps of radio frequency may be piled up to aid the detector, the signal which has failed to actuate the detector will NOT be heard. With radio-frequency amplification, on the other hand, there is no critical point, and even the weakest signal is built up to the desired degree before it is passed on to the detector, there to be rectified to audio-frequency current, which, if desired, may be passed on through one or more stages of audio-frequency amplification.

The illustration at the right shows a self-contained, six-stage radio-frequency receiver which provided the thousands who flock daily into that short, yet long, thoroughfare known as Wall Street, N. Y., with news of the moment. It was an experiment, but it worked out wonderfully. The radio set is mounted on an automobile, a 16-inch loop aerial providing the necessary completion of the circuit. The broadcast matter was carried to the crowd by means of the loud-speaker mounted on the shed of the car.

How the "New York Evening Post" "played up" the heading of its story of the "City of Honolulu" disaster.

WHILE she was 670 miles off San Pedro, California, fire broke out in the second-class cabin of the giant ocean liner of the Los Angeles Steamship Company's new Honolulu service, the "City of Honolulu," once a pride of the North German Lloyd. In some unaccountable way, the flames so advanced on the crew—which did heroic work in battling them—that in two hours it was found necessary to abandon ship. But before that command had been given by Captain R. H. Lester the vessel's radio had sent far and wide the call that means disaster, distress, and the possible loss of human life on the high seas.

Two ships, "Enterprise," of the Matson Line, and "Thomas," a United States Army transport, westbound, from Hawaii, picked up the signal and turned towards the position the operator had given. A pleasure yacht, the "Casiana," cruising to Honolulu, with her owner, E. L. Doheny and party of friends aboard, caught the appeal and turned her bow that way. Los Angeles caught the signals and Navy vessels stood by to race with death to the scene of the fire.

San Francisco caught the signals,

waited awhile until the radio operator on a distant ship had turned that vessel, too, towards the scene. It was that ship, the "West Faralon," M. M. Walk, master, that swept down the sea lanes to the "City of Honolulu" and effected the rescue.

But she did not get there until more than four hours after the flames had forced the captain, his first officer, the chief engineer, and the radio operator, who had stayed behind to serve to the uttermost the passengers confided to their care, to leave the blazing hulk. The officers stayed to advise, suggest, and confer; the radio operator stayed to keep the "West Faralon" advised lest she miss the boatloads of passengers floating near by and the rescue be delayed.

The chief radio operator of the "City of Honolulu" was W. H. Bell, of Oakland, California, who was making his first trip. The assistant operators were H. D. Hancock, Venice, California, and N. C. Kumler, Yakima, Washington. The three men remained at their posts so long as it was humanly possible. Mr. Bell is twenty-four years old.

Commenting editorially on the successful and remarkable part radio played in saving the lives of the passengers and crew in this latest of sea horrors, "The Times," New York, says:

Fortunately there was time to lower the boats and get everybody into them but the chief officers and the radio operators, whose duty it is to leave last and only when they are driven from their posts.

There must have been anxious moments for those in the boats, calm as the sea was. No smoke, no sail in sight. Many women and some children were among the passengers. Those vast waters appalled them. If help did not come soon, all knew the boats would not ride out a heavy sea. The comfort was in the thought that immediate response would be made to the radio signals—the nearest ship would come to the rescue under forced draft. Even so, it might be a race between her and the winds of the Pacific that at this time of the year sometimes rage on the briefest notice. But four ships, including the army transport "Thomas," picked up the call. It was the good luck of the freighter, "West Faralon," to be only fifty miles from the flaming ship and the waiting boats. She was perhaps four hours getting to the scene. Quick work was made in taking the castaways aboard. Sailors never spare themselves when a rescue is to be made.

In the old days of shipwreck without benefit of radio a rescuing vessel would probably have had to continue on her voyage to her first port of destination with the salvaged on board, but now there can be an interchange of messages between shore and ship. So it was arranged to have the "West Faralon" transfer the saved from the "City of Honolulu" to the army transport, permitting the freighter to proceed to the Dutch East Indies. As usual, the officers and radio operators of the abandoned vessel behaved with a gallantry and coolness expected of Americans beset by danger at sea. When the battle with the flames was lost the operator sent out his "Good-by" nonchalantly, and down into the boat he went, with the captain bringing up the rear of the little party.

The story is one to stir human emotions to the utmost—to make mankind thankful that radio is playing so important a part in the affairs of the world.

Vacuum Type of Arrester Safe

THROUGH proper publicity, the fear of danger in connection with radio sets has been greatly alleviated; indeed, to such an extent that some people have become exceedingly careless in rigging up their aerial and ground systems. Some believe that by simply disconnecting the aerial and letting it hang free they are assured of perfect protection. Though it is improbable that any damage would be done, this procedure is the least safe of all. Other people disconnect the aerial wire from their instruments and connect it to the ground lead. This is a safe but inconvenient method. One might forget to disconnect, with the result that some part of the set may be damaged.

The best method to pursue is to permanently connect some sort of lightning arrester—such as a vacuum, or air, gap—in the circuit between the aerial and ground. With such an arrangement, it is not necessary to change any connections during a storm or to think of grounding the aerial. Two metal plates mounted on an insulating base, so that the points are about 1/8 inch apart, will provide ample protection and be easy to make.

There are a number of worthwhile types of arresters on the market. Provide yourself with one and be absolutely safe. The lightning arrester forms a positive protection against lightning troubles and will operate indefinitely without attention.

The Radio Primer

For Thousands of Beginners Who
Are Coming into Radio Circles

*Weekly A B C of Radio Facts and Principles
Fully and Tersely Explained*

By Lynn Brooks

WHAT are the essential features of construction of the audio-frequency amplifying transformer?

The audio-frequency amplifying transformer consists of an iron core, around which are wound several thousand turns of fine insulated wires. The windings are in two parts—primary and secondary.

* * *

What is meant by primary and secondary?

The words are used to designate the two windings of the transformers. The primary winding is the winding into which the current is fed. It is generally marked on transformers by the letter P. It may be determined also by looking at the transformer. The smaller winding of the two is generally the primary, while the larger is the secondary. The secondary winding is marked S. It is the winding from which the transformed current is taken.

* * *

What is the iron core made of?

The iron core is made up of a large number of thin sheets of a special iron arranged in a square, or rectangle, thus forming a complete path for the magnetic force which is produced in the iron when the transformer is connected into the circuit of any radio-receiving-set.

* * *

What is the function of these transformers?

To change the audio-frequency variations in the plate circuit of the detector tube into the similar but greater variations in the grid circuit of the first amplifier tube. As a potential on the grid determines the strength of the signals heard by means of the phones in the plate circuit, the transformers make it possible to greatly strengthen these signals by increasing, or boosting, the potential impressed from the plate circuit of one tube onto the grid of the next.

* * *

What is meant by amplification?

Amplification means to magnify or enlarge. In radio it refers to the magnification of the strength, or loudness, of the signals received and detected.

The transformers just described are used in radio as magnifiers.

* * *

How are the radio signals amplified?

By the use of additional vacuum tubes and amplifying transformers. Instead of inserting the head phones in the output, or plate circuit, of the detector tube, the currents in this circuit are passed into a special transformer called the amplifying transformer. After passing through the transformer the signals are conducted to the grid of an amplifying tube. Being of a greater potential when they enter the tube through the grid, these currents liberate a large plate-current. Thus, if the head phones instead of being inserted in the detector plate-circuit are inserted in the amplifier plate-circuit, the signals heard will be many times louder.

* * *

How many times may detected signals be amplified?

Experimentally, without limit; practically, the strengthening of the signals is limited to two amplifying tubes.

* * *

Can amplifiers be used with regenerative sets?

Yes; but it will be found advantageous to insert a small bypass condenser around the primary winding of the first transformer.

* * *

What is the reason for this condenser?

The high-frequency resistance, or impedance, of the transformer winding is so great as to form a barrier against the passage of the retuned currents. A condenser allows the high frequency, or—as they are more often called—radio-frequency currents, to pass around to the grid without encountering this barrier.

Take Care of Your Phones

One thing that is important—dropping phones. This is apt to break the ear-caps and possibly injure the windings. It may injure the phones entirely. Receivers are built like a watch and should be given as careful attention. Take care of your phones and they will last you a long time.

How Crystals Change the Speed of Radio Waves

Thousands of radio beginners have come into the radio field since summer. They will find "The Radio Primer," published weekly in RADIO WORLD, a regular source of instruction and aid. For this reason, RADIO WORLD will republish, from time to time, some of the valuable primer articles that appeared in its early issues. These articles, by experts, contain a vast amount of radio information that cannot be duplicated. Every beginner will find them necessary to the building of sets and cooperative with the new material being printed.

BECAUSE of a peculiar property which they have of letting only part of an electric current pass through them all radio waves, when they pass through the air, are in the form of a wave, one-half of which is traveling in a positive direction while the other half is traveling in a negative direction, said a writer for this department in RADIO WORLD No. 6. This is illustrated in Figure 1. Now a crystal of one of the substances men-

Figure 1. Diagram of radio wave as it passes around through tuning coil and condenser. Solid-black part represents positive wave; cross-sectioned part the negative wave.

Figure 2. After passing through detector, wave of Figure 1 has been reduced to this form. The negative wave has been strained out by the crystal.

tioned above has a fondness for the positive kind of electricity, but won't have anything whatsoever to do with the negative kind. The crystal opens wide its door to the waves that are positive, but the door is slammed in the face of the other waves. This exclusiveness of the crystal is a fortunate thing for us. If the radio waves are trotting around our receiving circuit at a tremendous speed and we insert a detector in their path just one-half of all the waves will be rectified.

"Shielding" the Set

UNTIL the coming of the modern regenerative receiver, the term, "shielding," as applied to radio apparatus, was quite unknown. The regenerative receiver, however, being supersensitive to all electrical influences, has been found to require protection against external electrical disturbances. Shielding accomplishes this. It is the process of surrounding the entire receiver, and, frequently, the individual circuits therein, with a metallic surface. This generally takes the form of a copper lining in the cabinet and on the rear of the panel itself. Shielding takes care of the energy loss from the windings which tend to induce another current in the same manner that radio waves induce electric currents in a receiving antenna.

How to Make Your Aerial Function

By Horace Beers

ALTHOUGH any alternating current will cause a disturbance in the ether regardless of the size or shape of the circuit, in order to create the maximum disturbances possible with the power available, it is necessary to erect an aerial.

An aerial or antenna, as it is sometimes called, is a system of wire or wires stretched above the surrounding objects and connected to the radio set. The aerial is used for both receiving and transmitting, a switch or other transfer method being used to connect it to one or the other, according to the station sending or receiving the messages.

The wire used in aerials is either bare copper, phosphor bronze, or copper-clad steel. The ends of the wires are insulated with special insulators and the wire led into the house through an insulating tube known as a "bulk-head" insulator.

The problem of installing an aerial presents considerable difficulty to the beginner, but as a general rule, by bearing in mind just exactly what function an aerial performs, the problem is simplified. The average receiving set will operate with perfect satisfaction if a single wire—about size No. 14—100 to 150 feet in length is used. It is not absolutely necessary to have a fixed length. The wire may vary between 150 feet and 300 feet, and satisfactory results will be obtained.

The function of an aerial is to collect the electro-magnetic energy sent out from the transmitting station and convey it, through the receiving set, to the ground. As any conductor will perform a similar function, it is desirable that the aerial be suspended above surrounding objects. The electro-magnetic energy then reaches the aerial wire before it reaches any other object with the result that the receiving set receives more energy than would be the case if the wire were below surrounding objects.

In laying out an aerial, always endeavor to keep the wire level. If this is not possible, fasten the end from your receiving set as high up as practical and let the end from which the wire reaching to the receiving set is taken, be the lower end. Do not attempt to stretch the wire too tightly; it is of no particular advantage. It only raises the center of the wire a few feet and puts it under a severe strain which may result in breakage. This is especially true if sleet or snow collects on the wire.

In stretching the wire, try to eliminate as many bends as possible. Bring

Diagram of various types of aerials. The 4-wire aerial shown at the top is the inverted-L type, which may be used for receiving as well as transmitting. The two lower aerials are the inclined type. They may be used for transmitting messages.

the conductor leading to the set directly to your window without fastening it to the building. It is of great importance to keep this wire away from the surrounding objects, as there is a capacity effect between the wire and surrounding object which robs the aerial of some of its energy.

It is not possible to give specific di-

rections on the erection of aerials. Each particular house presents its own problem. With a little ingenuity an amateur may construct easily an efficient aerial in any place. In connecting aerial wires, be sure that perfect contact are made. When possible, always solder the connections.

This is important.

Accessories May Be Used to Increase Wave Lengths

THE average receiving set is usually capable of operation over only a comparatively narrow band of wave lengths. This should not be considered as a great fault, because sets can be more efficiently designed to operate over a narrow wave-length range than over a wide one. But occasionally it is desirable to hear stations that operate on wave lengths higher or lower than those afforded by the tuning apparatus of a set. Sometimes an aerial may be too long to work with a certain set to hear the shorter waves and some means must be provided to cut down the natural period.

An accessory that may be attached to a set to increase its wave length in order to hear some of the longer wave stations is called a "loading coil." This is connected in aerial and ground.

When a two-circuit receiver is used, another coil must be connected in series with the secondary in order to balance the two circuits. When a loose coupler is used, a moderate amount of loading may be used in the primary circuit without any in the secondary, as the secondaries of these instruments are usually wound with more wire to compensate for the slight loading. If a shorter wave than the natural wave-length of the aerial is wanted, some sort of condenser may be connected in series with the aerial circuit. This condenser is usually of the variable air type, though it can be of the fixed variety. Where a short-wave condenser is used, a single pole switch may be provided so that when it is not needed it can be short circuited without any trouble.

How to Avoid Interference when a 360-Meter and a 400-Meter Station Are Operating Simultaneously

By *C. W. Horn,*

Superintendent of Radio Operations, Westinghouse Electric & Manufacturing Co.

THE U. S. Department of Commerce, in order to assist radio broadcasting, has specified two wave lengths on which broadcasting may be conducted. These wave lengths are 360, the one in general use up to this time, and 400, just recently allotted. While these wave lengths are 40 meters apart, there will undoubtedly be considerable confusion on the part of those owning radio receivers who are situated in close proximity to one of the stations. For the purpose of assisting those who are so unfortunately located that two such stations are picked up by their receivers simultaneously, I will describe a number of methods which, if applied, should greatly assist those desiring to get either one of the two waves without being too greatly interfered with by the other. There is one case, however, which will be very difficult to assist, that is where the receiver is exceptionally close to a broadcasting station. By close is meant within a few thousand yards.

The assignment of two wave-

lengths so closely together will have the effect of stimulating construction of radio apparatus which will be capable of tuning more sharply, and it is the old case of "necessity is the mother of invention." Therefore, while there may be some inconvenience at the present time, this should be overlooked in order to help the radio game by creating a condition which will stimulate the construction of better apparatus and which will permit, perhaps, in the future the assignment of more wave lengths, thus creating a better situation in the air.

One of the greatest faults that the writer has found in connection with the installation of radio-receiving apparatus is that it is believed that the more wire and the larger the antenna, the more will be received. Exceptionally large antennae make it more difficult to tune sharply, and for this reason it is advocated that very short single-wire antennae, approximately 75 feet long measuring from the apparatus to the far end, be utilized, such single-wire antennae to be stretched

away from all metallic objects and run straight and clear of all obstructions.

Secondly, do not run the antenna or the lead-in over metal roofs, along water spouts or drains, or parallel to telephone and power wires.

Frank Conrad, assistant chief engineer of the Westinghouse Electric & Manufacturing Company, has made measurements and drawn resonance curves which show that a short low antenna tunes much more sharply than a large and long antenna. This holds true both for coupled and single-circuit tuners.

Another method to pursue in overcoming interference, especially where vacuum-tube receivers are used and where the receiver is located close to a broadcasting station, is to make use of the well-known directional properties of the loop antenna. A very simple loop may very easily be constructed by winding a half dozen turns of wire, spaced about one inch apart, on some framework, which can be rotated. It will then be easy to tune out a station which has a difference of 40 meters in wave length, especially so as a loop antenna forms a closed circuit which can be more sharply tuned than an open antenna. Both ends of the loop should be connected across the antenna and ground terminals, and no other ground or antenna used.

Radio enthusiasts who are more fortunately located—that is at but a short distance from a broadcasting station—may tune, without any difficulty, in either one of the wave lengths mentioned. They should, however, bear in mind that a single-wire antenna, not too long and kept free from obstructions, and not running near grounded metallic objects, will tune sharper. Where the amateur has a transmitting apparatus it is desirable to have a fairly large antenna, with more than one wire. If such is the case, he should use a separate wire for receiving.

The ideal condition will be when stations can operate independently on either side of two wave lengths without interfering with each other. Because the receiving apparatus is an important factor these suggestions are given in order that owners of receiving apparatus may have the necessary information to increase the efficiency of their apparatus.

In a New York Y. M. C. A. Radio School

(C. Kadel & Herbert)

Operator William Pacquet sending a message in the radio school of the Y. M. C. A., New York. This school possesses some of the most up-to-date radio apparatus in the country. It is utilized for practice on commercial transmitting and receiving. The transmitter is at the left; the receiver at the right.

Another R-W Page of Hook-Ups

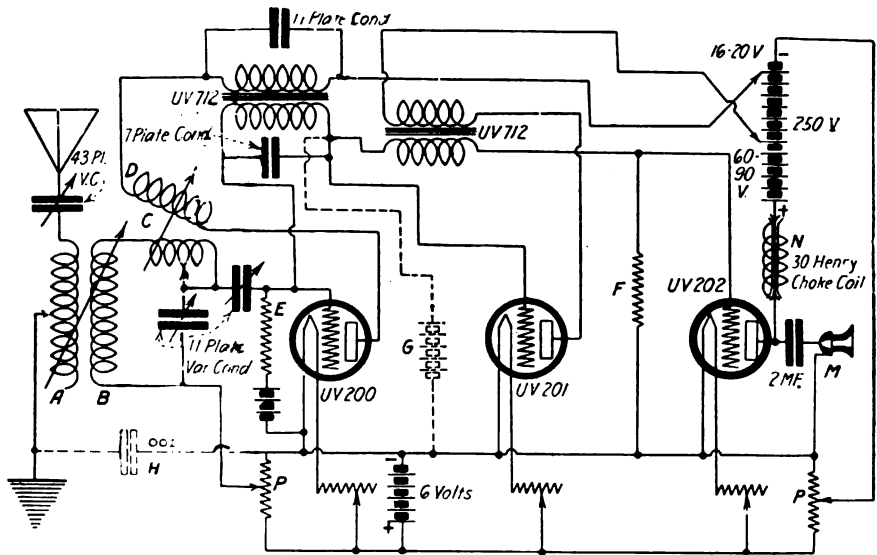

Schematic diagram showing common type of transmitter used in low-frequency tube sets. In this circuit, the microphone modulates on the grid of the tube. This is a very good telephone transmitter. Drawn by C. White.

Schematic diagram of a set in which the tickler coil is employed as a direct feedback. Two tubes are used—one as a modulator, the other as the oscillator. A very satisfactory circuit for C-W work, especially for amateurs. Drawn by C. White.

A unique method of employing regeneration is detailed in the above circuit. This is of the single circuit type. It also utilizes a tickler coil and is hooked in the circuit. Suggested by John Kent. Drawn by S. Newman.

Schematic diagram of a practical circuit, employing the following apparatus: A-B is a vario-coupler; C-D is also a vario-coupler having a wave length from 180 to 900 meters. The tickler is wound with 125 turns of wire (bank wound). E is a variable grid-leak, $1\frac{1}{2}$ to 3 volt bias. F is a fixed grid-leak of about 1 megohm. G-H shows optional connections, the grid bias being from 6 to $22\frac{1}{2}$ volts. M is a loud speaker. N is a door-bell transformer (primary open) using 110 volts as chokes. Suggested by Dr. O. S. Kelly. Drawn by S. Newman.

Realizing that the most interesting phase of radio with the average "fan" is the testing out of hook-ups, Radio World will publish, from time to time, a page of the most interesting diagrams, some of which have already appeared in its pages. An editor guides his policy by the wishes of his readers, and the number of requests for back numbers containing these diagrams indicates that there is an insistent demand for them.

Schematic diagram of a regenerative circuit employing a tickler coil as means of regeneration. The dotted lines show how the magnetic lines of force act about the primary winding of the receiver and the tickler coil. Suggested by Fred Chas Ehlert. Drawn by S. Newman.

Single-slide tuner employing, as means of detection, a crystal detector. This type receiver is capable of receiving broadcast programs about twenty-five miles. Suggested by Horace Beers. Drawn by S. Newman.

Radiograms

Latest Important News of Radio Garnered from the World Over, and Reduced to Short Wave-Lengths for the Busy Reader.

N. O. 64 BROAD STREET, New York City, the building to be purchased by the Radio Corporation of America for \$1,000,000, is known in the radio world as the "heart of world-wide wireless," as from here there are more circuits handled than in any other place or country in the world. The building itself is ideally located for the purposes of the company, because it is in the center of the financial and commercial district of New York from which a large percentage of the traffic handled originates. The building is within two blocks of the principal cable and telegraph forwarding offices and particularly near the Postal Telegraph Company's office with which the Radio Corporation has recently entered into a traffic arrangement whereby the Postal Company collects and distributes trans-Atlantic radiograms from and to all points in the United States. The building is ten stories high and contains 43,000 square feet. It is known as the White Oil Building, but the name, in all probability, will be changed to "Radio House." It will be remodeled to meet the needs of the corporation and to house the executive, sales, and engineering departments of the corporation, now located in the Woolworth Building.

* * *

Dr. Samuel Wesley Stratton, for the past twenty-one years director of the United States Bureau of Standards, and one of the leaders in radio legislation and standardization, was elected recently president of the Massachusetts Institute of Technology. He will take up his new duties on January 1, 1923.

* * *

During the next six years more than three hundred billion dollars will be spent in the additional electrification of America, said Frank E. Watts, New York, editor of the "Electric Record,"

He Telephoned by Radio from San Francisco to London

(C. International Reel Photo)

H. GORDON SELFRIDGE, JR.,

Son of the London merchant, was photographed in San Francisco, while telephoning by radio to his father, in London, 6,000 miles away.

in an address to the annual convention of the National Association of Electrical Contractors and Dealers. "The possibilities of electrical development are unlimited," said Mr. Watts. "Eight million homes in the United States are now wired for electricity, six million are not. Half of those will be wired within the next few years. How rapidly the central power stations are expanding is indicated by the fact that, last year, the light and power companies spent \$750,000,000 in new development. And in the next six years they will spend a total of four billion dollars to extend their electrical service to the homes and factories in America."

* * *

President Alfredo Zayas of Cuba has formally inaugurated radio broadcasting in Havana. His speech announcing this important event was delivered in the national palace and shot out into space from the sending station of the Cuban Telephone Company. Special transmitting apparatus was installed in the palace to carry the president's voice from that place to the radio room of the telephone company. The wave length used was 400 meters. The station was erected by the International Telephone and Telegraph Corporation of New York. Experimental tests made in Havana developed the fact that amateurs in the United States as far north as New Jersey were able to hear phonograph records broadcast from Cuba.

* * *

Captain Pownatan Page, vice-president and general manager of the Pan-American Wireless Telegraph and Telephone Company of Buenos Ayres, who has been in New York City negotiating international radio connections for his \$156,000,000 South American plant, says that a misapprehension has arisen through a paragraph which said "the combined plants represent an invested capital of \$170,000,000." "This is perfectly true, of course," Captain Page said, "but certain readers appear to have inferred that cooperation in operating resources involved also a combination of this huge capital under one board—in short, that the world's leading radio concerns had formed a trust. What I desire to make plain is that the figure \$170,000,000 represents the combined capital of all the radio interests mentioned, which is in no way affected by the international cooperative plan. Each company is as separate and distinct in its own sphere as before and absolutely directs its own affairs. The finances of the various radio companies concerned are not combined, as appears to have been understood in some quarters."

* * *

The United States Government now maintains ten broadcasting stations for the purpose of sending out crop and market news.

* * *

A feature of the Closed Car Show at the Grand Central Palace, was a radio-equipped automobile which operates without antenna and ground wires, a condenser made up of a copper screen and the chassis forming the wave collecting system. This car, a limousine, had the distinction of being the only machine at the show so equipped. One plate of the condenser, a copper screen, is fixed between the roofing and upholstery, thus completely concealing it from view. The metal parts of the machine, being all joined together, form the other plate of a large condenser, having air and passengers as a dielectric, the separation being about five feet. The preliminary tests of this apparatus proved that such an application of radio reception is highly feasible and very satisfactory.

* * *

It has been suggested that the President of the United States set aside ten minutes each day for a personal radio talk with the American people.

* * *

By operating on two different wave lengths, one 450 metres and the other 350 metres, a two-way radio talk was successfully carried on between Portland, Oregon, and Los Angeles, California.

* * *

Broadcasting descriptions of missing persons is now one of the most important uses to which radio is being put.

* * *

Radio insurance is now being offered, covering fire, lightning, breakage and theft.

* * *

French children are turning from mechanical toys to miniature radio sets. These tiny sets are being turned out in large quantities by French manufacturers.

Radio and the Woman

By
Crystal D. Tector

I WAS in the train from New York City to New Rochelle, the other day, and two women were chatting in the seat behind me. One of them remarked, "Well, women are in everything, to-day, even radio." She almost took my breath away—indeed, I nudged Friend Husband with sufficient force to jar him from his afternoon paper and, turning, looked the speaker squarely in the eye. I presume that the look on my face betrayed my surprise; but, realizing that I had put myself in a position to be criticized, I mustered every bit of courage at my command and asked: "Are you interested in radio, madam?"

* * *

"Oh, I have to be!" she exultantly exclaimed, as soon as she realized that I did not intend to be rude by my sudden intrusion.

Then we "got together," as the men say, and most formally introduced ourselves; and I whirled F. H. about in his seat and introduced him too. And my new acquaintance proved to be a most charming person—an instructress of radio classes in girls' private schools. Her brother, she said, was radio officer on a steamer in the Pacific, and he had told her so much about radio that she "just took to it as a duck takes to water," as she tersely put it. All that she knows her brother taught her; but she is putting the knowledge to the most practical use—making it earn her a living.

* * *

And why shouldn't radio appeal very strongly to women? It does seem to me that but few of its elements—if any—are beyond the reach of our sex. And, this week, I am pleased to show you a picture of Clara Kimball Young, who we all know as one of the most attractive of "movie" stars, actually putting together her own set. No doubt, any woman who cares to go deep enough into the mysteries of radio will be able to do the same thing. When we take into consideration the fact that little children are among the most ardent radio fans—that they seem to master its apparent intricacies—there is no reason why we grown-up women should hesitate to become fans, too.

* * *

I am told that radio is one of the most attractive things ever put before the little ones. I am told that no mother—or father, for that matter—should deny the little ones their right to become

(Melburne Spurr, photographer, Los Angeles)

"Clara Kimball Young actually putting together her own set. Any woman who cares to go deep enough into the mysteries of radio will be able to do the same thing."

(G. Paine & Atlantic Photos, Inc.)

Miss Betty Bates, the California violinist, and the transmitting set into which she played music that was carried by radio to Havana.

Betty Bates, the San Francisco violinist, whose music, played in the City by the Golden Gate, was heard in Havana. Over 13,000 fans reported having heard her. Her music was sent over a 5,000-mile radiophone circuit connecting Havana, Cleveland and San Francisco. Miss Bates is a violinist of considerable merit whose playing by radio was a broadcasting event.

* * *

Here is a little advice in answer to many inquiries:

In all radio-frequency amplifying circuits it is absolutely necessary that a potentiometer be used across the A battery which lights the filaments of the tubes. This stabilizes the entire circuit and enables the operator to put the proper amount of negative on the grids of the radio-frequency tubes. This function will be further assisted by placing a by-pass condenser of at least .001 mfd. capacity across the grid lead and negative side of the potentiometer.

* * *

(The following letter is self-explanatory. We are pleased to gratify our correspondent's wish, though if her communication had arrived an hour later the presses would have started.—The Editor.)

Dear Mr. Editor:—I have just received this week's copy of RADIO WORLD and I am so enthused over your suggestion for a National Radio Week that I immediately phoned Friend Husband to his office and told him that we would certainly give a radio party during that week—a really big party to which mostly strangers to radio will be invited. You may count on me for all the help I can give. I think that the different broadcasting stations should announce it in some good slogan like, "Are you prepared for National Radio Week?" once a day, until the event gets started.

Yours for "The Big Week."—C. D. T.

interested in this wonderful science. Just what is the particular psychology that makes it appeal so strongly to children, I do not know. Perhaps some of you mothers can tell me. Nevertheless, it is a fact that radio does possess some far-reaching interest for the little ones that—like electricity itself—cannot be explained.

* * *

I am glad to see that the broadcasting programs have their quota of women artists. But I want to tell particularly about Miss

Latest Radio Equipment for N. Y. N. G.

By Walter Miller

(Both photographs C. International News-Reel)

THE newest radio aids used by the radio detail of the 71st Infantry, National Guard of New York, are shown in the accompanying illustrations and the illustration on the front cover of this week's issue of *Radio World*. The 71st Infantry is a licensed station with the call BY4. Sending and receiving is accomplished at the same time by using the loop antenna for reception and an outdoor cage-antenna for transmitting. BY4 sends both telephone and telegraph signals and has been heard throughout the Eastern United States.

The upper illustration shows the interior of the radio room of BY4. The lower illustration shows how sending and receiving are accomplished simultaneously, on seventy meters, by the loop set. A break-in system is used which gives instantaneous message traffic without the necessity of throwing a send-receive switch.

Instructors who have qualified as experts in their respective lines, are in charge of the various classes; and the men of the battalion are enabled to enjoy the best of instruction and training.

Lieutenant Grant Layng is in charge of the radio work of this detachment of the 71st. An excellent opportunity is open in this organization for radio operators and other technical men who desire a radio education; but because of the limited number of men designated for the detachment those selected finally must qualify thoroughly both technically and in a military sense. Drills and classes are held on Tuesday night and Friday night of each week. Applicants should apply to the Armory, Park Avenue and 34th Street, on either night.

"Close-ups" of Recent Radio Devices

(C. Kadel & Herbert News Photos)

One of the most important elements in radio is the proper circuits in working out a telephone broadcasting-station. During the recent World Series it was most important that all the circuits were of the correct value. In order to accomplish this, each line had to be tested out. The above photograph shows the new special-type of voltmeter for testing the voltage by which messages were sent to WJZ for broadcasting.

(C. Kadel & Herbert News Photos)

In radio work, the storage battery plays an important part. One of the first things the amateur is taught is an understanding of its functioning, and, also, how to take care of it. The storage battery is a necessary element in radio and one must know its main parts. The above photograph shows C. A. Peterson, director of the Department of Electricity, at the Y. M. C. A., New York, explaining a new battery.

(C. Kadel & Herbert News Photos)

John Frazier photographed speaking into the very latest thing in microphones. Mr. Frazier was sent by the Westinghouse Company, Pittsburgh, to assist New York City experts in the broadcasting of the recent World's Series. His object was to see that no energy was lost in the transmission lines.

The photograph below shows the Finch radio relay. It is a very recent radio invention which automatically receives and records code messages on paper tape—messages which may be read as reports are read on a stock ticker. All that is necessary is to connect the radio relay to a radio receiver. It will record and retransmit messages simultaneously.

(C. Photomews, N. Y.)

(C. Kadel & Herbert News Photos)

This little device tucked under a table in the operating room of WJZ, Newark, plays a most important part in the successful broadcasting of big news events. The telegraph wire carrying the news enters WJZ at this point, and the above device, consisting of resisting coils and transformers, eliminates all distortions on the line. This is a great relief, as it lessens all that unnecessary tinkering which is experienced in the phones when receiving. From this point, the line enters the speech amplifier and from the speech amplifier it is transferred to the modulators, thence to the aerial. Contrary to the belief of many, a second microphone is not used in broadcasting an important news event, such as the recent World's Series.

Secret Lines of Radio Communication

By Carl H. Butman

WASHINGTON, D. C.—Back of the commercial systems of world communication, known and used by both government and private interests, lie existing lines of communication little known to the public although not strictly "secret." Only recently, when the "Terrible Turks" threatened the Dardanelles and Southeastern Europe, the State Department asked the Navy if aid could be given in the transmission of dispatches to the Near East in the event that communication service to that quarter of the globe was broken. To this question, which caused the State Department some concern, the Naval Communications Service made reply as follows: "Our lines of communication to the embassy at Constantinople and all our naval craft in Turkish waters are established and in official use to-day. We can communicate with Admiral Bristol within a few minutes."

It has been stated justly that naval communication circles the world. So it does, with the exception of very few corners, and three-fourths of the communication is handled by radio.

To-day, when a dispatch for Admiral Bristol is filed in the Navy Department, it goes out at once through the Annapolis radio station to a French radio station, thence by land line to the office of the American Communication Service operated by naval personnel in Paris, where it is checked and forwarded by wire to Coblenz. The message is relayed electrically at Coblenz from the office of the Chief Signal Officer of the American forces in Germany, where Army operators handle the wires to Vienna. The Vienna station is in the Austrian Telegraph Building, but the station is operated by the United States Navy. From Vienna the message goes forward by naval radio service from the station at Laareburg direct to the receiving station at the American Embassy at Constantinople, where naval personnel again handle the dispatch and forward it to the naval ship on station there, which relays it to its destination. Admiral Bristol is in charge of all American naval vessels in Turkish waters, and the presence of his destroyers makes a sort of fan to all points of which messages can be relayed by radio and delivered from the vessels to other points. In the event of a break in the wires from Paris to Vienna, messages for Constantinople would be radioed by French stations to Vienna and to United States naval vessels in the Mediterranean.

The route of messages from points in the Black Sea to the United States is similar, except that the outlying ship transmits by radio to Constantinople, either to the station ship or the Embassy, but only the ship can send messages. From the station ship the message goes by radio to Vienna, thence to Coblenz by wire and through to Paris, where dispatches are turned over to French Radio Service for

transmission, either from Lyons or Lafayette, to Bar Harbor and delivered by land wire to the Navy Building in Washington.

This system, though seemingly somewhat roundabout, is nearly direct and is good except that it is subject to delay on account of schedules, as the Allies all use the same route in and out of Constantinople and keep it busy twenty-four hours a day.

The "Dashboard Special" Makes 40,000 Mile Tour, Equipped with Radio

(Both photographs by General Photographic Service, N. Y. C.)

An automobile with a loop aerial in front of the wind screen and a receiving set on the dashboard recently made its appearance in the streets of New York. Crowds gathered wherever it stopped and listened to the music of broadcasting stations. Mr. and Mrs. J. C. Davenport, owners of the car, were testing out their new radio set, known as the "Dashboard Special." They had just completed a forty-thousand mile tour and were about to leave on a second tour of indefinite duration. The upper picture shows the "Dashboard Special" in front of the Pennsylvania Station, New York City. The lower picture shows Mr. Davenport and the arrangement of his car's fine radio equipment.

"Kamoi" Claims Prize Radio

*Japanese Naval Craft, Experts Say, May Now Boast
Finest Installation*

"KAMOI," fuel ship of the Imperial Japanese Navy, which steamed out of New York recently, en route to Japan, on her maiden voyage, has the most elaborate radio-equipment of any other ship afloat, according to radio engineers. The most recent inventions in the field of radio art have been included in the outfit, the greater part of which was furnished by the General Electric Company.

Included in the transmitting equipment are a 1-kilowatt radiotelephone and radiotelegraph set which may be used for telegraphy on continuous or interrupted continuous wave; a 20-kilowatt telegraph transmitter and a 2-kilowatt 500-cycle quench spark-transmitter for telegraph only.

The reception equipment comprises a long-wave receiver with a range of from 1000 to 30,000 meters and a short-wave receiver ranging from 200 to 7000 meters. In addition, there is a superheterodyne receiver for long and short waves, and a standard three-tube commercial-ship receiver with a range of from 200 to 7,000 meters.

An interesting feature of the installation is a radiotelephone exchange, by means of which the ship's operator can transfer control of radiotelephone transmitter and receiver to any one of several stations. These stations are located in the commander's room, the commander's office, the senior officer's ward room, and the bridge. By means of the telephone exchange, the commander, or any other officer, may communicate with any vessel in the fleet from any one of the sta-

tions on the "Kamoi." The exchange board differs very little from the usual telephone exchange. A red light indicates that the receiver has been taken from a phone hook, and the operator, by throwing a switch, puts the officer in immediate control of transmitter and receiver.

There is also a radio compass by means of which it is possible to find the direction of distant transmitting stations.

The "Kamoi" is the show ship of the Japanese Navy. She was recently completed by the New York Ship Building Corporation, and is the first vessel of any navy, other than the United States Navy, to be electrically propelled. The electric-drive equipment was designed and installed by the General Electric Company. The "Kamoi" is a 20,000-ton, 8000-horsepower vessel, and will make fifteen knots. Her main propulsion unit consists of an 8000-horse-power Curtis turbine generator which supplies power to two 4000-horse-power synchronous motors directly driving the twin-screw propellers. There are also two 400-kilowatt direct-current turbine generators which supply the excitation current as well as power to operate the auxiliaries, such as the main circulation pump, main condensate pump, sanitary pump, and blower motors. Another feature of the propulsion equipment is a 625-kilowatt auxiliary alternator which can be connected to either of the auxiliary turbines in case of the failure of the main driving-unit. This small generator will supply sufficient power to drive the ship at a speed of seven knots. The "Kamoi" will be used to carry coal and oil to ships of the fleet.

Experts Plan Big Radio Constructive Campaign

TO aid the government and the American people in peace or war, to eliminate the confusion of rapid development, to work with the Federal departments to devise a rational scheme of broadcasting for the Nation, to promote on a universal scale effective organization of all radio instrumentalities, and in general to undertake at once the solution of the pressing problems of the industry, now leading to conflict," are the declared purposes of the new National Radio Chamber of Commerce.

In a statement yesterday announcing the practical completion of the task of selecting the executive personnel of the chamber, which includes the appointment as general counsellor of Henry T. Hunt, No. 111 Broadway, late member of the Railroad Labor Board and former Mayor of Cincinnati, it was said that a committee had been appointed to investigate the whole question of broadcasting. One of the first steps in the committee's work will be to hold an open meeting of the chamber in Chicago during this week at the Chicago Radio Show.

William H. Davis, the president of the chamber, at its headquarters, No. 165 Broadway, summed up the chamber's general attitude toward broadcasting as follows:

"The only scheme of broadcasting which can prevail in any real sense is one in which the end to be attained

reconciles all conflicting elements, even to the submerging of private interests."

The vice-president of the chamber is Harold J. Power, the secretary, George Lewis, and the treasurer, Lloyd Marshall. The board of governors consists of A. H. Grebe, Richmond Hill, N. Y.; C. B. Cooper, New York; A. P. Morgan, New York; B. L. Moore, Buffalo; J. R. Crawford, Long Island City, N. Y.; E. R. Harding, Boston; Boden Washington, New York, and Gordon Sleeper, New York.

A plan of regional organization has been adopted by the chamber with the following district vice-presidents:

First district (Boston), O. K. Luscomb, Cambridge, Mass.; 2d district (New York and Northern New Jersey), to be elected; 3d district (Philadelphia, Baltimore, Washington), Atwater Kent, Philadelphia; 4th district (Atlanta, Savannah, Jacksonville), to be elected; 5th district (New Orleans, Memphis, San Antonio), to be elected; 6th district (San Francisco, Los Angeles, San Diego), Colin B. Kennedy, San Francisco; 7th district (Seattle, Portland, Tacoma), Robert H. Mariott, Seattle; 8th district (Pittsburgh, Cleveland, Toledo, Detroit, Cincinnati, Columbus), Powell Crosley, Jr., Cincinnati; 9th district (St. Paul, Milwaukee, Chicago, Indianapolis, St. Louis, Kansas City, Minneapolis, Denver), Harry Bradley, Milwaukee, and Dr. C. F.

Type R-3
Magnavox Radio
with 14-inch Horn

Why
MAGNAVOX
RADIO is

The "Reproducer Supreme"

MMAGNAVOX Radio is not manufactured to help sell one make of receiving set, but to complete the service of every good quality wireless station.

1. **Universal Use:** The Magnavox can be used with any receiving set—the better the set, the better can Magnavox operate.
2. **Simplicity:** The hook up is as simple as that of the ordinary telephone headsets.
3. **Volume:** With the Magnavox, the volume of sound is limited only by the amount of power input.
4. **Tone:** Official tests with the oscillograph prove that the Magnavox electrodynamic receiver reproduces incoming wave forms with maximum accuracy.
5. **Quality:** In refinement of workmanship, materials and finish, Magnavox products have no rivals in their field.
6. **Construction:** The electrodynamic principle involved in its construction makes Magnavox Radio the most efficient converter of electrical vibrations into sound waves.

The Magnavox Company have been pioneers in the development of devices for scientific sound amplification. When you purchase a Magnavox Radio or Power Amplifier you possess an instrument of the very highest quality and efficiency.

Latest Radio Patents

Coupling for Radiotelegraphy

No. 1,427,350. Patented, August 29, 1922. Patentee: Joseph Bethenod, Paris, France.

THIS invention, on which M. Bethenod has been granted letters patent, both in France and the United States, refers to an improved system of coupling between radiotelegraphic antenna and a high-frequency alternating-current generator of the type of those susceptible to furnishing, directly, a current of the frequency necessary for the feeding of the antenna. This system is applicable outside of any combination re-

Mr. Bethenod's invention will be more easily understood by reference to the above diagrams. Figure 1 represents the fractioning of the winding of the alternator and the manner of tying with the antenna by means of independent coupling transformers; the Figures 4 and 5 each represent a modification in the mounting of the secondary windings of the transformers. Figures 2 and 3 represent, respectively, front and side view, the manner of preferred execution for the independent transformers. Figure 6 represent the manner of assembly of the various transformers used.

quired by the difference of phase that may exist between the currents engendered in the different notches of the armature and can be perfectly realized with a monophasic alternator. The inventor's chief purpose is to avoid, in such a machine, having the insulators stand an exaggerated tension; the means used is to fractionate the winding into several sections by taking the precautions indicated in the manner of the tying of these sections to the antenna so that the machine may not be the seat of internal circulation currents.

Mr. Dubilier's Condenser

No. 1,429,227. Patented, September 19, 1922. Patentee: William Dubilier, New York, N. Y.

A CONDENSER adapted to assume any desired capacity value between maximum and minimum limits, and more particularly to a condenser in which the above is accomplished by combining the capacity of a condenser of the fixed type in which the plates bear a permanent

Figure 1 is a perspective view somewhat diagrammatically illustrating a condenser adapted to operate in accordance with Mr. Dubilier's invention. Figure 2 is a detailed view showing a modified form of fixed condenser adapted to be used in place of the fixed condenser illustrated in Figure 1.

and fixed relationship to each other, with the capacity of a condenser of the variable type having a plate or plates shiftable in position as regards plates of opposite polarity to vary its capacity—this is the basic principle of Mr. Dubilier's invention.

The fixed condenser is made up of sections, or units, which may be cut into or out of circuit to obtain what may be termed stepped capacity-values over the desired range of the instrument, and the variable condenser is arranged to supplement the capacity of the fixed condenser in order to obtain the resultant capacity values which are intermediate the values obtainable by adjustment of the fixed condenser alone.

Mr. Dubilier intends to provide a condenser of the above type which may be adjusted to cause the capacity to rise or fall progressively and uniformly, or which may be adjusted to produce a straight-line curve in capacity changes, and, in its preferred form, a single operating member is provided which serves both to adjust the capacity of the fixed condenser to different values and to shift the capacity of the variable condenser in such manner that, substantially throughout its entire range of movement, changes in capacity are effected substantially proportional to the amount or degree of movement imparted to the operating member.

Electron-Discharge Circuits

No. 1,426,526. Patented, August 22, 1922. Patentee: Harry C. Egerton, Passaic, New Jersey.

THIS invention relates to circuits for electron-discharge devices and pertains more especially to audion circuits. Its object is to improve the operation of vacuum tubes, such as the audion. The principal parts of an audion structure are a heated filament, or other source of

electrons, an anode and an electrode, preferably located intermediate the filament and the anode, the electrode being usually called the grid. These are preferably enclosed in an evacuated glass-vessel. The main characteristic feature of the audion is that the amount of the space current flowing between the filament and the anode is dependent on the potential of the grid electrode.

It has been found, however, that, when the grid is made considerably more positive than the filament, the tube operates less efficiently and an excessive positive charge may even cause the tube to "blue-haze," or to be destroyed. This is due to the fact that the grid, on becoming appreciably more positive than the filament, tends to become even more so through secondary electron emission by the grid, this secondary electron emission being caused by the bombardment of the grid by electrons. However, even if the grid does not acquire a charge sufficient to injure the vessel, the charge may hinder the action of the tube in the

Figure 1 represents a vacuum tube of the audion type having its input circuit connected to the source of oscillations by the transformer, and having its output circuit connected by the transformer to a suitable outgoing line or consumption circuit. 12 is a source of current for the output circuit. With such an arrangement the transformer will impress upon the outgoing line, amplified oscillations of the form impressed on the input circuit. Figure 2 shows how the internal structure of an audion may be modified to conform with the purpose of this invention. 3 illustrates the invention in connection with an oscillation generator. In order to prevent the grid from becoming sufficiently positive to cause the tube to "blue haze," or generate oscillations of an undesirable complexity, the electrode of the unilateral device is connected to the grid and the filament to the filament.

case of a repeater or amplifier by starting free oscillations in the tube circuits. Such free oscillations would be undesirable also where the tube was employed as an oscillation generator.

In order to overcome these difficulties, it is proposed to afford a leakage path to the filament for the positive charge on the grid by connecting a unilateral impedance between these two electrodes in such manner as to allow current to flow from the grid to the filament, but not in the opposite direction.

Moving Picture Manager Objects to Radio

UNDER the heading, "Detroit Papers Rebuked by Trendle, Kunsky Manager," "Moving Picture World" publishes the following:

The following letter was sent recently by George A. Trendle, manager of the John H. Kunsky theatres, to the Detroit Free Press and the Detroit News:

"I have recently learned that the Government desires to curtail the operating of the radio broadcasting station of both your paper and the Detroit Free Press, and understand that in the very near future you will be called into conference for that reason, and am taking the liberty of again writing, in the hope that you will seriously consider the advisability of discontinuing the use of the radio outfit after 7 o'clock in the evening.

"We are spending many thousands of dollars with your publication each year to increase the attendance at our motion picture shows. Undoubtedly it is a self-ish motive, but at the same time, an expensive one, while your publication at no profit to itself, makes a strenuous effort to keep as many of our patrons away as possible by giving them lavish entertainments during the evening, without expense. This does not seem to our organization to be a fair and just return for the co-operation we are giving your paper, and if you can eliminate the broadcasting during the evening hours, giving your patrons the benefit of it during the afternoon or morning, I am sure that you will eventually benefit by it.

"I am writing the Free Press and making the same request, not as a favor, but as a strictly fair and square business consideration, to which I feel that the theatres of Detroit are entitled in return for the enormous amount of advertising placed in your publication from week to week. Comments are heard from theatre managers daily with reference to this, and it certainly deserves some consideration on the part of the News.

"I sincerely hope that after careful thought you will agree with me that the News can carry its message to its many radio fans without so seriously interfering with the operation of amusement enterprises in Detroit, which, I am frank to say, have not come back to normal since the inception of the News and Free Press radios. Our residential houses particularly have been seriously affected and we can give no other reason for it."

New Broadcasters Licensed

THREE new broadcasting stations were licensed during the past week:
KFDD—St. Michael's Cathedral, Boise, Idaho.
WNAP—Wittenberg College, Springfield, Ohio.
KFEB—City of Taft, California.

Only One Licensed Broadcaster in Berlin

There is only one licensed broadcasting station in Berlin at present, and this sends out mark and exchange quotations. Service charges range from 1,000 to 7,500 marks a month, to which must be added the cost of the Government license and the installation of a receiving set.

Electrical Club Starts Radio Class

THE Electrical Jobbers' Club of New York has organized a class in the practical and technical features of radio, open to any electrical contractor-dealer in the metropolitan district of New York City, or any of his men. No charge is made for tuition. The work covers merchandising, installation, and operation of radio sets.

A Persistent Advertiser

Robinson Crusoe advertised for a ship. His medium was of most limited circulation and had no A B C rating; but he got the ship.

Mr. Crusoe did not get immediate results. His advertisement flapped on the pole till the rains and winds tore it to shreds. But he renewed his "ad." In fact, he gave his last undershirt to his faith in persistent advertising; and through his persistence, Robinson Crusoe's name will be handed down from age to age.

You, too, will get satisfactory results and create a trade name of permanent value by persistent advertising.

Our suggestion is that you give RADIO WORLD a 52-time order obtaining our minimum rate of \$4.25 per inch by using a one-inch rate holder and larger space as desired. Among RADIO WORLD'S 70,000 readers we believe are numbered more radio manufacturers, live dealers, and enthusiastic fans than could be reached for double the money in other radio publications. For full details address RADIO WORLD, 1493 Broadway, New York.

Our Quick-Action Classified Ads., at five cents a word, bring big results in one week after receipt of copy.

Heard at the Radio Counter

A Conversation Between Customer and Radio Clerk

(Part II)

SAY, John, did you hear that 'bird' last night working C. W. with a note like a willow. Oh, boy! If I only had another tube in the circuit, believe me! I would have heard him all over the room."

"Yes, I guess you are right on that; because just when WJZ shut down for a few minutes, I started in tuning for whatever stations I could pick up. The first thing I knew, this 'bird' started up—but it was sure a good note."

"What do you consider a good audio-frequency transformer? I would like to add another step in the circuit."

"Here, this is a good make. I am using them and get wonderful results. Just try one and see what happens."

"All right—and, by the way, give me a tube socket, also."

"Have you any need for an extra B battery, rheostat, or leak condenser? You know, these will be needed when you add the extra tube."

"I guess you better let me have them. Also, better give me about two yards of spaghetti tubing. Now, there is one question I would like to ask before I go. What is the best method to determine the strength of my storage battery? I think I need some acid."

"Just a minute. What you need is this instrument—a hydrometer and holder. It will tell you the exact condition of your battery. See where it is marked 1275? This means that your battery is O. K., and needs but little charging. Now, when the hydrometer shows 1150, or even 1200, just say to yourself, 'I better put this baby on charge before it goes to the dogs entirely.' One good thing to remember: Never let your battery fall below 1225."

"Very well. Wrap up the hydrometer, too."

"See you again, O. M."

(To be Continued)

Coming Events

The editors of RADIO WORLD will gladly publish news items of all contemplated radio shows and expositions. Keep us posted by mailing full information.

SECOND NATIONAL RADIO EXPOSITION, direction International Trade Exposition Co., Chicago, January 13 to 20, inclusive, 1923, George A. King, director of publicity, 417 South Dearborn Street, Chicago, Ill.

PERMANENT RADIO FAIR FOR BUYERS, Hotel Imperial, New York City. Open from September, 1922, to May, 1923.

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, December 21 to 31. Colwell & Korbell, Fisk Building, New York City, directors of publicity.

TRI-STATE TOBACCO GROWERS' RADIO SHOW, Covington, Ohio, October 21 to 28, inclusive.

INTERNATIONAL RADIO SHOW, Madison Square Garden, New York City, November 20 to 25, inclusive. E. C. Buchignani, director of publicity.

SOUTHEASTERN RADIO EXPOSITION, Auditorium Armory, Atlanta, Georgia, December 4 to 9, inclusive. Co-operative Radio Sales Assn., 295 Peachtree St.

WANTED: COPIES OF RADIO WORLD, April 22 and May 28, 1922. Mail us copies of these issues, or either one, with an accompany postal and we will send you a copy of the latest issue for each copy so mailed. RADIO WORLD, 1493 Broadway, New York.

Navy Radio Sets Bring \$43,000

THE opening of bids by the United States Navy Surplus Sales Office revealed the fact that 47 firms and individuals were interested in the 390 radiotelephone sets offered for sale re-

cently. The highest bid received was \$251 for one set; the total receipts reaching \$43,000. The awards made were as follows:

Limits Radio Talk to Coastal Areas

Norwegian Government Says Ships in Territorial Waters Must Observe Strict Rules of Radio Communication.

THE following regulations regarding the use of wireless stations on vessels belonging to foreign powers not at war, while in Norwegian territorial waters in times of peace, have been approved by government resolution, and came into force on September 1, according to the "Anglo-Norwegian Trade Journal."

1. In Norwegian territorial waters wireless telegraph or telephone stations on foreign vessels may not be used, except by special permission, unless for the following purposes:

- (a) Communications concerning vessels in distress or for the prevention of accidents.
- (b) Communications; (c) communications with the nearest Norwegian coastal station, and other ships' stations when each vessel is at least ten nautical miles distant from the nearest Norwegian coastal station.

In the cases of (a) and (b) communication must at once be stopped on request from the Telegraph Administration, the Naval Department or a station belonging to either of these authorities.

2. In Norwegian ports where there is a state wireless station and within certain prohibited districts laid down by the Norwegian authorities (regarding which information may be obtained from the nearest state coastal station), the ships' station may not be used except for communications as under 1 (a) unless special permission has been obtained.

3. Application for permission to use a station in Norwegian territorial waters for other communications than above mentioned should be sent to the Telegraph Administration (Telegrafstyret), which will give its decision after consultation with the Naval Administration.

4. (This paragraph concerns war.)
 5. When a ship's station is used while in Norwegian waters this must be done with the observation of the provisions

of the International Telegraph Convention and its regulations.

6. The foregoing regulations remain in force only when Norway is not at war.

Textbook on Radio

THIS 350-page volume deserves the most unqualified praise for the thoroughness in which the publishers have endeavored to cover the interests of the radio enthusiast. There are a number of valuable suggestions in its pages which will be of value to both fan and amateur. It is written in a simple style, and, at the same time, it is a standard textbook for the technical radio student. It contains, the up-to-date material regarding circuits and hook-ups including data on superregenerative receiving sets. This book can be secured from your dealer or direct from the Technical Book Co., 130 West 42nd Street, New York City.

YOUR PHOTO IN THIS PAPER

ATTENTION AMATEURS!

Have you built your own receiver?
 Are you experimenting with any particular hook-up?
 Are you improving your set?
 Are you doing any interesting constructive work in radio?

Why not share this knowledge with your thousands of brother fans who read RADIO WORLD every week?

We want pictures of receiving sets with descriptions of how you overcame some difficulty, or of any additional part or unit that you have added to obtain better results. These are the things that, probably, the other fellow is looking for. Send in your information; pictures or whatever you have done to improve the art.

Remember the beginner is looking for them.

We intend to print in this paper, each week, pictured information and description of value to radio amateurs. If you have found a newer or better way of doing anything, don't keep the secret but tell it to your thousands of brother fans.

Send in a photograph of your set with or without accompanying diagrams and measurement. State whether you figure in the picture yourself, or not, and without any expense whatsoever to you we will make an engraving and publish it. Be sure to write your name and address plainly on photograph.

Send in your picture at once, or if you have not made a set or done anything else in making radio material, tell the boy next door all about this offer.

Radio May Rob Volcanoes of Terror

PROBABLY never again will Vesuvius belch its fires of destruction upon an unprepared and unsuspecting populace, or Popocatepetl rain its death-dealing lava upon unprotected Mexican

peons, says Raymond Francis Yates in "The Evening Mail," New York.

Scientists and the wonderful vacuum tube of the everyday radio receiving-set are seeing to that.

Work of applying sound amplification to the study of volcanic activities within the earth has already reached the advanced stage. In fact, there has been constructed a device so sensitive that the moving waters of subterranean springs easily can be recorded by it.

This apparatus, which might be called the "sound microscope," is so tremendously sensitive to air vibrations that it permits one to hear things heretofore absolutely inaudible.

It is destined to become as great an aid to hearing and acoustics as the microscope and the telescope have been to vision.

SOMETHING NEW!

P. O. Box 44

Patent Applied For

Does Good Work With Low Power

NIGHT by night, throughout the breadth of the land, there takes place a series of communications under the most efficient organization ever produced by voluntary methods, says "The Tribune," New York. The development and operation of this system are the work of the average American radio amateur, under the executive guidance of his national institution—the American Radio Relay League.

The work of this organization has to a certain extent been obscured in the phenomenal advance of public interest in radio due to the advent of broadcasting, and only occasionally does an inkling of its achievements appear.

Before outlining this, however, it should be pointed out that the amateur owning a transmitting station is restricted to a maximum output of one kilowatt of power by the government. Many of the amateurs are still further restricted by the exigencies of their financial standing, but they make up in enthusiasm what they lack in funds.

To still further understand the contribution of the American amateur to the development of radio as a means of communication, it should be stated that he also is compelled to work on 200-meter wave length as a maximum, where the frequency of the oscillating current is so tremendously high that it offers almost insurmountable difficulties.

Despite these obstacles, he has succeeded in communicating across the Atlantic Ocean with less than one kilowatt of power, where under the same conditions the big transatlantic wireless stations are compelled to use 200 kilowatts. This is unquestionably his crowning triumph.

Day by day he maintains a network of communication across the country which has already proved its worth in cases of emergency and which is becoming more efficient every day. In addition, he also maintains a daily communication between the Pacific Coast and the Hawaiian Islands with the low power allowed him by the government.

For CORRECT RADIO MAILING LISTS Use THE POCKET LIST

of Radio Manufacturers, Jobbers and Dealers in the United States and Canada. Issued Quarterly—January, April, July and October. October, 1922, issue corrected to September 15th, 1922. Classified under three different headings—Manufacturers, Jobbers and Dealers—and alphabetically arranged by states, cities and towns and names of firms. Containing approximately 15,000 names and addresses.

We have been exceptionally careful to see to it that every Manufacturer, Jobber and Dealer is listed and under the PROPER CLASSIFICATION. Most mailing lists concern charge more than \$100 for a list of this kind and, as a rule, those supplied are far from being correct. Compare this list with any other, and you will find it to be the very best obtainable anywhere at any price.

October issue ready for distribution September 25th. Price \$5.00 per copy, or \$10.00 per year (four issues, including monthly supplements which keep the list absolutely correct and up to date at all times). October edition limited. Send your order with remittance today.

For Building Radio Apparatus at Home

THANKS to the Radio Research Laboratory of thoughtful Uncle Sam, three pamphlets on the construction and operation of radio receiving apparatus have been released for radio enthusiasts through the Bureau of Standards and the Government Printing Office. These supplementary circulars now give data and instructions on how to improve the previously described sets with auxiliary apparatus which can be constructed at home at a small cost. A limited number of the circulars are available at the Bureau.

Circular 46 describes two "fixed" condensers which are used with either of the radio receiving-sets described in the first or second circulars. One of the fixed condensers, which is connected in series with the antenna, is called the "series-antenna" condenser. The other fixed condenser, which is connected across the terminals of the telephone receivers, is called the "telephone-shunt" condenser.

The series-antenna condenser enables the receiving equipment to give signals of somewhat greater intensity when tuned to wave frequencies above 1000 kilocycles per second—that is, wave lengths of 300 meters or less. The effect of this condenser is just the opposite of the effect obtained by a greater number of turns of wire on a tuning coil, which permits the receiving equipment to respond to lower wave-frequencies.

The effect of the telephone-shunt condenser is to increase the intensity of some radio signals to which the receiving set may be tuned. In most cases the use of this condenser has no effect upon the intensity of signals which are received from a radiotelephone transmitting station, but it will increase the intensity of radio signals which are received from most spark transmitting stations. The cost of building both condensers is not over 80 cents.

Circular 47 describes a loading coil which is used in conjunction with the single-circuit radio receiving set described in Bureau of Standards Circular No. 120 or with the two-circuit set described in Circular No. 121.

The purpose of the loading coil is to enable the receiving equipment to respond to wave frequencies between 100 and 500 kilocycles per second—that is, wave lengths between 300 and 600 meters. In other words, the loading coil increases the wave-frequency (wave length) range of the receiving set. The receiving set described in Bureau of Standards Circular No. 120 has a wave-frequency (wave length) range of between 500 and 1500 kilocycles per second (wave lengths between 600 and 200 meters).

The use of this loading coil will increase the receiving distance of the equipment, because many stations using the lower wave-frequencies (longer wave-lengths) use a high-power radio transmitting set. For example, NAA, Arlington, Virginia, uses a wave frequency of about 113 kilocycles per second (2650 meters wave length) and uses sufficient power to be heard a distance of about 200 miles when the loading coil described is used with the receiving equipment previously described. The cost of the parts for the loading coil is approximately \$3.

Reliable and Beautiful
RADIO-A
RE-CHARGER

THE RADIO-A is a highly efficient dependable piece of apparatus, absolutely fool-proof, easily attached by simply plugging into ordinary 110-volt lamp socket. In case of current failure, the unit cuts out automatically until current is resumed, without discharging battery.

It is designed expressly for re-charging radio filament batteries, but may be used for automobile or any other storage battery of reasonable size and capacity.

Price, \$18.50

Dealers and Distributors

Here's a Winner! Write us for full particulars.

Simply screw into any 110 volt lamp socket and connect the terminals to your battery. Impossible to hook-up wrong—RADIO-A charges either way.

A compact portable Re-charging Unit that will fully charge a 100 A. H. Battery overnight, for from 5c to 10c, according to prevailing rates.

Answers to Readers

I AM building a set with a crystal detector. May I use enameled wire on my tuner and taps? Has enameled wire insulating qualities?—Eugene Martens, Glen Cove, Long Island, N. Y.

You can use No. 22 enameled wire very nicely for the winding of your tuner and taps.

* * *

Will I hear Newark, Pittsburgh, and Schenectady with the enclosed hook-up and apparatus as listed?—Yearle Travis, Tuckahoe, N. Y.

Your hook-up is almost completely useless. You will not be able to hear anything with it as it is shown. Our best advice is that you read carefully the article by C. White, "Constructing a Radio-Frequency Regenerator," in RADIO WORLD, Vol. II, No. 2, dated October 7. This circuit applies to your ideas.

* * *

How far can I receive with a De Forest receiver, type DL-800, with two-stage amplifier? What length should my antenna be and in what direction should it be run to get best results? Will another stage of amplification enable me to receive further?

Which should I use—2000-ohm or 3000-ohm phones? Would two or more sets of receivers have any bad effects on my machine?—Arthur Walsh, Patchogue, L. I.

Your first question is too broad to answer; but with a good antenna satisfactory results should be obtained. Your antenna for receiving should be one straight wire about 100 feet long. The direction should be from where the lead-in starts. One more step of amplification will increase the volume and distance of your signals, but it is hard to say just how much distance this one stage will increase. You can use either the 2000-ohm or 3,000-ohm phones; but, remember, only one set may be used at one time.

* * *

Can two sets receive from the same aerial? Are all audion bulbs guaranteed to work? Where can I buy an electric soldering-iron? What is the price?—Radio World Reader.

Two sets cannot be used from the same aerial unless they operate at different times; otherwise, the tuning of one set would affect the tuning of the other. I do not believe that all audions are guaranteed to work, but if you buy one of the standard makes it is quite sure to give you satisfactory results. You can buy an electrical soldering iron in any electrical or radio shop for \$7.

* * *

Can a loud-speaker be used with a crystal detector?—John Rogers, Bedford, Mass.

A loud speaker cannot be used with a crystal set. Don't try it. It will not operate. At least two stages of amplification are necessary.

* * *

My receiving set consists of a single-wire antenna about 200 feet long, a loose coupler, two variometers, grid leak, vacuum tube and grid condenser. With this set how far should I receive? If I added a two-stage amplifier, how much further could I increase my range? I also have mounted on my set a shielding made of copper sheet, which has no effect on tube howling.—George Siegel, Coldwater, N. Y.

With a set of this description some operators have heard the broadcasting stations over some distance, using but one tube. In your case no exact distance can be given as this is right up to the operator himself. There is no doubt in our minds that you should at least hear WGY, Schenectady, New York. From other stations near you we have had reports that the following were heard, using one tube: KDKA, Pittsburgh; WJZ, Newark, N. J.; WBZ, Springfield, Mass. The addition of a two-stage audio-frequency amplifier will make these stations louder. We suggest that you connect the copper shield to the ground connection in order to eliminate the tube howling and other noises.

* * *

I added a two-step amplifier to my Westinghouse receiver. Will you please tell me how I can add to the wave-length range so that I may tune, say, up to 1,500 meters? Howard Mitchell, Galveston, Texas.

As the set you have is designed to do certain work, it is doubtful if you will be able to raise the wave length. You might try inserting a large single-slide tuning coil in the aerial lead before it comes to the set. This, possibly, may help you a little; but it is very doubtful. Certain sets cannot be loaded up successfully.

* * *

In some honeycomb coil hook-ups, the bridging condenser is connected from the positive side of the B battery to the filament; in others, it is connected from the filament direct to the plate. Which is correct? (Continued on following page)

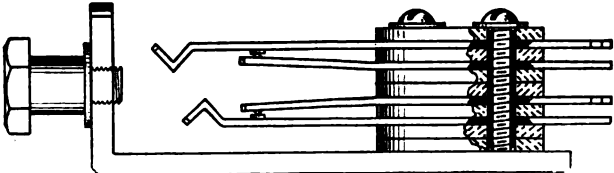

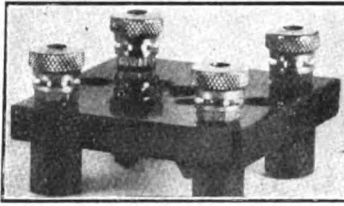

Subscribe for Radio World, \$6.00 a year, \$3.00 six months, \$1.50 three months.

Answers to Readers
(Continued from preceding page)

rect? Can a .001 condenser be used for the primary condenser instead of a .0015 condenser? Does choke-oil amplification eliminate distortion?—Raymond Finch, St. Louis.

The bridging condenser may be connected in the circuit in either way. Both circuits are correct. The primary condenser should be .001 mfd. capacity for best results. Choke-coil amplification will not eliminate distortion. Improperly adjusted circuits have more to do with it.

* * *

Is it necessary to have an aerial running east and west in order to hear Pittsburgh and Schenectady?—Leslie Meyers, Passaic, New Jersey.

It is not absolutely necessary to have an aerial running east and west in order to hear these stations. If the aerial is extremely long, it may help you a little to aim the free end of the aerial toward the transmitting station; but it will help very little.

* * *

What is the constant for the phone fixed-condenser used in connection with the Armstrong superregenerative circuit? What size vario-coupler should be used with the superregenerative? Can ordinary dry batteries be used for the C battery?—Thomas Meegan, Stapleton, N. Y.

The capacity of the phone condensers should be .0025 mfd. Any standard vario-coupler having a range from 150 to 600 meters. The secondary must be rewound twice the number of turns. Two flashlight batteries connected in series should be used with the first two tubes and a 22-volt battery with the third tube.

* * *

I would like to know what a two-slide tuning coil looks like? I intend buying one of these coils and want to know what I am purchasing.—Arthur Hanson, Phoenix, Ariz.

Diagram of tuning coil requested by Arthur Hanson, Phoenix, Arizona.

Above is an illustration of a tuning coil with two slides. This is used in connection with a receiving set as a means of the inductance in order to establish the necessary wave-lengths needed.

* * *

Why must I use 120 volts or more to operate my detector tube?—Peter Gray, Duluth, Minn.

Probably you have a hard tube—one with a fairly high vacuum. This is similar to a vacuum tube of the transmitter type and works best on a high voltage. However, it will not be very sensitive at best.

That Armstrong Circuit

So much interest has been displayed in the special article, "TESTED INVENTION OF MAJOR ARMSTRONG AMPLIFIERS SET 100,000 TIMES," by John Kent, that appeared in RADIO WORLD No. 13, dated June 24, 1922, the publisher decided to put aside a number of copies for those who were not able to get this issue when published. Copies will be sent, postpaid, on receipt of 15c. or send in your subscription, \$6.00, for one year (52 issues), \$3.00 six months, or \$1.50 three months, and subscription will be started with the issue containing the article about Major Armstrong's Amplifier.—RADIO WORLD, 1493 Broadway, New York.

Want to Know All About Aerials?

Send 15 cents for a copy of RADIO WORLD, No. 23, dated Oct. 7.

This number contains an article on the erection, care, size, and style of aerials.

It is informative, practical, and simple. It is brief and to the point.

It was written by C. D. Wagner, a radio expert.

Entered as second-class matter, March 28, 1922, at the Post Office at New York, New York, under the act of March 3, 1879.

IMPORTANT NOTICE:
 While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Mysterious Radio Metal

THIS metal of mystery was discovered by Berzelius in 1817, says "The Globe," New York. It has taken a hundred and some odd years to perfect it to such an extent that it is one of the most useful and promising of substances in the hands of the scientist, inventor, and experimenter. One, F. V. Madaler, has spent the past fifteen years of his life in research work on this metal at his selenium laboratories, and he has built cells of utmost sensitivity for all types of work in which such cells may be used. It is through this man that most of the data here included was obtained. Selenium is produced in two different forms: in rods and in powder. They are of different colors—reddish brown and black. When melted it has the consistency of sealing wax, and is of shiny black. When it is in this condition, it is practically a nonconductor, but by passing through a chemical process, it will change in color and become partially conductive, and will be very sensitive to changes in light. That is, its resistance will change, in a degree depending upon the amount of light reflected on it. At first, or in the dark, the resistance of the selenium is very high, and it gradually decreases to a small fraction of this resistance as the intensity of the light increases.

Don't's for Listeners

DON'T fail to insulate the antenna. Don't place the lightning switch indoors.

Don't listen in during a thunder storm. Don't cause interference with other stations.

Don't try to use a loud speaker with a crystal set.

Don't run wires parallel in making up receiving sets.

Don't neglect to read everything available on radio.

WESTERN ELECTRIC power Amplifier, practically new, complete with tubes and horn. Cost \$161.00. Will sacrifice for \$120.00, \$30.00 down, Balance, C. O. D. **Roscoe E. Magee**, Box 71, London, Kentucky.

REGENERATIVE RECEIVER—two step amplifier, complete in cabinet, \$35.00. **C. D. Lowndes**, 2607 Wylie Ave., Pittsburgh, Pa.

ASTONISHING results Rokay Regenerative Hook-up without use of Variometers—variocouplers, switches, taps, etc. **ONE SINGLE CONDENSER CONTROL ONLY.** The coming receiver. Simpler than a non-regenerative—better than any regenerative we have tested. Hook-up, \$1.00. Money Orders only. Saves you \$10.00 in building your own. With properly wound coils \$3.50 post paid. Complete receiver parts on wood base with Vacuum Tube, \$8.00. Head set and "B" Battery, \$21.35. Express paid. **Rokay Electric Co.**, Ingomar, Ohio.

VARIOMETERS AND VARIOCOUPERS, \$3.00 each. Can Handle any number of orders. **Ralph R. Garrick**, 126 North Redfield St., Philadelphia, Pa.

MURDOCK PHONES—type 56, 3000 ohms... \$5.50
MURDOCK PHONES—type 56, 2000 ohms... \$4.50
U. V. 200 (Detector tube)..... \$4.50
U. V. 201 (Amplifying tube)..... \$5.25
Postpaid in U. S.
Send 25c for 208-page radio manual and catalogue. **A. V. Gregory**, 42 Broad St., Redbank, N. J.

DO YOU USE A CRYSTAL DETECTOR? ARE YOU MAKING A CRYSTAL RECEIVER? Increase the efficiency of your crystal detector 1,000 per cent by using a "PT" Ultra-Sensitive Contact. Of special gauge and alloy; makes and holds a quick, ultra-sensitive, stable, adjustment. Endorsed by **RADIO WORLD**. Using galena, you may pound panel or table without disturbing sensitivity in slightest. Proved practical on shipboard by an oldtime Marconi operator. Using a "PT" Contact on galena, Arlington (NAA) was brought in clear at 3,300 miles (below the Equator); and Arlington came in loud at 2,200 miles (of Dutch Guiana). In both instances, nearby ships using vacuum tubes were unable even to hear NAA. As to stability, Cape May (WCY) was worked over 1,000 sending right through crystal with 2 KW spark, without affecting detector's adjustment. Replace your insensitive unstable spring or catwhisker with a Contact which will hold its adjustment in addition to giving louder signals and music. Indispensable for use in your crystal set, regardless of make. A novice can install. "PT" **ULTRA-SENSITIVE DETECTOR CONTACT**, with instructions, twenty-five cents, coin or M. O. "PT" **CRYSTAL CONTACT CO.**, Box 1641, Boston 8, Massachusetts.

Broadcast Bill's Radiolays

(Copyright, 1922, Westinghouse Electric & Manufacturing Co.)

I'M glad it's gettin' cooler now, fer all these distant stations are comin' in lots better; an' since my wife's relations have packed their trunks an' journeyed home perhaps I'll get a chance to listen undisturbed by noisy chatter of her aunts. Last night I picked up Davenport an' Kansas City too, KDKA came in real loud, but, say, I wish I knew who tried to queer the program with a string of that there code; I'd like to bust his doggone set an' run him down the road. That's not the only QRM I'm gettin' here to-night, cause Willie's in the kitchen puttin' up his weekly fight. It bein' Saturday, you know, Young William's tub comes first an' next to dryin' dishes Willie hates his bath night worst. Then, after he's been put to bed, his mother takes her turn, an' when she's through I reckon, if you'll excuse me, I'll adjourn out yonder to the kitchen 'fore the water gets too cold, an' get the dern thing over with. I hope that Min won't scold if I set there an' lissen to some Military Band while I work with the scrubbin' brush, removin' soil and sand. We may not have a fancy tub with water runnin' hot, like some of our rich friends around the neighborhood have got; but bathin' set to music ought to start a brand new style—I guess I'm goin' to like it if I'm lis'nin' all the while. When I build my

new bungalow I'm goin' to have a set built right in close beside the tub so I can always get the latest news an' gossip an' perhaps a tune er two; 'tain't such a bad idea an' there's one thing sure, it's new.

Subscribe direct or through your news dealer. \$6.00 a year, \$3.00 six months, \$1.50 three months. **Radio World**, 1493 Broadway, N. Y. C.

GOLD MEDAL San Francisco 1915

GRAND PRIZE San Diego 1916

Again the engineers of the Radio Guild lead the field in the production of radio necessities that meet with the approval of the foremost authorities.

“Multi-Range” (Bank Wound Coupler)

Passed the strict requirements of the RADIO NEWS LABORATORIES and awarded their Certificate of Merit.

Pronounced by the “N. Y. Evening Mail” Laboratories as “the finest bank wound coupler produced” and awarded their Certificate of Excellence.

Scientifically designed by experts, the “MULTI-RANGE” Coupler permits the easy construction of an efficient short and medium wave receiver at low cost. Wave-length Range 150 to 3,400 meters.

Specifications

Bakelite Tubing; green double silk covered wire, wound by hand and moisture proofed; heavy nickel-plated metal parts; convenient solder taps; 180° coupling; Litz wire rotor leads.

List Price, \$11.00

DEALERS: The “Multi-Range” Coupler is widely advertised. Write for special discounts.

Radio Frequency Set Operates in Interior of Automobile

THE day may arrive when the radio sets capable of receiving music clearly from distant points, will be reduced to the simplicity of one knob for tuning; for the present, however, simplicity exists only in the inexpensive receiving sets for the reception of radiotelephone and radiotelegraph signals, at short range. When it comes to receiving sets for long range, satisfactory results may be obtained only from elaborate equipment; and the more elaborate the apparatus the greater the care and skill required for its successful operation. Take the simple receiving sets, for example; there is little or nothing to master in the way of operation. Such sets generally have a multipoint switch to control the wave length and detector. If a crystal detector is used, it must be accurately adjusted for the utmost sensitiveness and this necessitates care. Of course, there are the tubes with audio-frequency and radio-frequency hook-ups. The radio-frequency type of receiver employing vacuum tubes is coming into general use among experienced amateurs for long-range reception. The loop aerial comes in connection with such a set. In the case of audio-frequency amplification, the amplifying is done after the signals have been passed through the detector and rectified so as to produce audio-frequency currents, while the radio-frequency amplification of the waves are amplified before they are passed to the detector.

The advantage of the radio-frequency amplifier lies in the fact that it amplifies only the wave and not the many little irregularities and imperfections which exist in the usual receiver and amplifier equipments.

The upper photograph shows a radio-frequency set made by Peter Smancy, a Newark amateur, to operate in an automobile owned in Lavalette, New Jersey, a town claimed by experts as "dead"

to all radio signals. Although expensive sets with big aerials had failed to get a signal, this small portable outfit using an 18-inch loop for an aerial brought in Newark and Pittsburgh so clearly that music could be heard by persons twenty feet from the head sets. The complete set is shown in the lower picture. It utilizes three

stages of radio-frequency with a detector and three steps of audio-frequency for amplification. The loop aerial may be seen with the layout and home-made horn for loud signals. This set has been carried in this car for some time. With it the most satisfactory results have been obtained by using radio-frequency as a means of amplifying.

(Both photographs C. Underwood & Underwood, N. Y.)

Detectors—and How They Work

By Donald Van Wyck

THE popularity of the receiving-set has caused a great many fans and amateurs to become interested in the broader aspect of radio. Not a few are familiar with electricity and handy with tools, but a large majority of them do not even care to learn the elementary principles of the game. The layman seems to think that all that is necessary is to connect up the set and it will gladly do the work. This is a great thing of which to boast. Many sets will work, but it is a question whether or not a set is working to its fullest efficiency. A little experimenting along well-developed lines may enable the beginner to greatly improve the strength of received signals.

The multiwire aerial, of course, is a waste of time and money; but the single wire cannot be beaten for receiving purposes. However,

This diagram is the simplest way of showing a two-element tube detector. It is the original Fleming invention and acts as a rectifier in much the same way as does the crystal.

the direction in which the aerial points, as well as the location, has a lot to do with the matter. The direction will not make a great difference in the receiving; but, in radio receiving, the currents dealt in are so small that anything that will help in the least to make the signals louder may well be looked into. The direction that the aerial should be pointed is, of course, towards the station to be received.

The ground lead is another important factor in the set. Some amateurs are using several grounds, such as cold-water pipe, gas pipe, radiator, and the outside private ground. All of these grounds may work well together or may not work at all. No definite rule can be

laid down, because conditions will vary greatly with the locality.

The purpose and usefulness of the detector is to convert the received current of high frequency into the direct current necessary to operate telephone receivers. Various forms of detectors which accomplish this end have been used in the past, including the original coherer, the magnetic detector the electrolytic, crystal, the vacuum tube detector. All of these, except the two last mentioned, have become obsolete. We have previously read in RADIO WORLD that the crystal detector makes audible the high frequencies of incoming signals because it rectifies them. In other words, it allows the current to pass only in one direction. This rectified current consists of a series of pulsations which pass through the windings of the telephone receivers and cause the diaphragms to vibrate, at a frequency which, in the case of radiophone signals, would correspond with the tones of the music or voice being sent out. We have also seen that, for long-distance reception, a detector having more sensitive and stable characteristics than the crystal type is very desirable. These desired features are embodied in detectors of the vacuum-tube type.

When using the vacuum tube as a rectifier it must allow passage of the received alternating current in one direction and prevent the passage of current in the opposite direction. To bring about this result, it is obvious that something must be done to lower the resistance of the tube for current flowing in one direction and keep the resistance high when the current tends to reverse. The two metallic parts, or electrodes, are securely sealed into the glass tube and the tube is then pumped out until it is almost entirely free from air. One electrode, the plate, is generally formed of thin sheet-metal, while the other, known as the filament, is made of small wire and has both ends brought out through the glass. By connecting the two ends of a battery to this filament, it can be heated by the battery current to a temperature which will cause it to glow brightly. When the filament is thus heated, the space between it and the plate becomes a conducting path for the flow of current if the voltage on the plate is positive; but the resistance is maintained to pre-

vent the flow of current if the voltage on the plate is negative. In this way, as with the crystal, a pulsation current is produced which vibrates the telephone diaphragm and produces sound. The sensitiveness of the vacuum tube is greatly improved by the use of a third electrode, called the grid, which is essentially a metallic screen of fine mesh. This screen is placed between the plate and filament of the tube and connected into the circuit as shown. Its function is to control the flow of current from the plate to the filament, through the telephone circuit.

It will be seen that, besides the A battery for heating the filament, there is also a plate battery called the B battery. This is connected in series with the telephone receivers so that the positive ter-

The three-element vacuum tube is shown here. The X in the circle represents the grid which makes the vacuum tube the most sensitive rectifier of radio signals. The third element, or electrode, is the work of Dr. Lee de Forest.

minal is next the plate and the negative terminal is next the filament. When the battery is connected in this way, there is a steady flow of current from the B battery through the tube. This current may be controlled by applying a small voltage between the grid and filament. When the voltage on the grid is negative, it has the effect of decreasing the current in the telephone circuit; and when the grid voltage is positive, it allows the plate current to increase. In this way, the feeble alternating currents of an incoming signal may be applied to the grid and filament and used to control the flow of direct current from the B battery through the telephone receivers. Thus the effect of the signal is multiplied through the relay action of the tube and produces considerably greater action of the telephone receivers than could be obtained by simple rectification.

Hermit Radioist of Canadian Wilds

By Peter Gray

THE unique circumstances and exceptional radio accomplishment of M. J. Caveney, a lonely trapper with a penchant for companionship by radio, should stir the admiration of all radio enthusiasts. Mr. Caveney occupies a cabin at Sandy Falls, near Timmins, Northern Ontario, Canada. He has assembled one of the most powerful radio sets. It includes a complete transmitter and a receiving layout. The accompanying photograph shows the interior of Mr. Caveney's radio shack. To the left of the receiving set, to the right is the transmitting gear.

An oscillation transformer makes it possible for Mr. Caveney to insure amateurs that he can give them sharp coupling, which, in turn, will bring sharp tuning at the receiving end. Mr. Caveney claims that with this spark transmitter, he has reached and communicated messages to amateurs within twenty-five States of the United States. This the trapper can prove by the collection of postal cards, shown in another picture. In looking over the list, most amateurs who have heard Mr. Caveney were from the eighth and ninth districts. Yet there may be read the call letters of some from the third, fourth, and fifth districts. Some very fine work of transmission, indeed!

Mr. Caveney no doubt intends to keep plastering his walls with postal cards from radio amateurs who listen in when he is using his transmitter.

Probably his transmitter may be heard at a greater distance when the transatlantic tests are being made in December. If so, this would prove the importance of utilizing radio as a means of long-distance communication between amateurs.

(C. Underwood & Underwood, N. Y.)
Mr. Caveney's set. He calls this corner of his cabin his "radio junk shop."

Italy Demands Radio

THERE is a growing interest on the part of the Italians in American production of radio apparatus. Inquiries are being received both for transmitting apparatus to be used in broadcasting and for radio telephone receiving sets. If American manufacturers interested in the possibilities of the Italian market for their product will send catalogues and other descriptive literature to the office of the American Commercial Attache, care of the American Embassy, Rome, such material will be made available to all persons inquiring.

(C. Underwood & Underwood, N. Y.)
A few of Mr. Caveney's radio post cards. Nearly every American radiolist who has "heard him" has sent him a card—and he has quite a collection.

(C. Underwood & Underwood.)
The cabin where C. J. Caveney, Canadian trapper, spends twelve months of the year—and it looks like this the long winter round. But Mr. Caveney is not lonesome. His radio set keeps him in touch with so much of the rest of the world that he has a goodly quota of conversation and entertainment when not engaged in his interesting occupation.

Working Right!

Jimmy—You take this wireless receiver I just finished making, and go down stairs in the cellar; hold it close to your ear and listen.

Freddy—(after waiting in suspense for several moments in the cellar)—Aw—it's a fake; I didn't hear a thing.

Jimmy—Good! That shows it's workin' right. I didn't say anything yet.

One of the Most Delicate Parts of a Receiver

By George W. May, R. E.

Figure 1—Schematic hook-up of the vernier rheostat. A is the grid circuit. B the grid of the tube. E the plate of the tube, C the switch. D the A battery. F the rheostat. G the potentiometer and arm.

THE detector tubes now on the market require careful attention and correct adjustment of the plate battery for satisfactory results. As a matter of fact, here are no two tubes possessing the same characteristics either in filament current or plate voltage. It is very easy to make adjustments on the filament, since the rheostat gives very fine control of the current. Vernier rheostats may be purchased. These vernier rheostats have an extra arm built on the same shaft as the regular arm, and it travels over a single fine wire tightened around the body of the instrument. This is very practical as it enables the operator to regulate the filament temperature *very* closely which, sometimes, is very desirable.

The high-voltage batteries may be purchased tapped; the battery should, in fact, be tapped. Changing the number of cells in a B battery would change

the positive potential on the plate. If the positive potential on the plate became greater, it would have a greater attraction for the flying electrons in the tube; hence, in a given time, more electrons would arrive at the plate and be pumped around the circuit by the battery. Such B batteries as are used for this change of high potential are of the high-voltage type, as previously explained. They have five or more brass strips on binding posts secured into the sealing compound. Each one of these cells is connected to a cell in the battery. So by connecting with the different posts, different values of voltages may be obtained.

Jumping from one post to another on the battery may be done by employing a clip; but it is much more convenient and easier to put five contact points and a switch arm on the panel of the receiver and so be able to vary voltage by simply turning the switch arm. Of course, this necessitates a little hard work, but it is compensated for by the ease and rapidity with which tubes may be tested to determine the relative efficiency of different makes.

The connections are shown herewith. Each strip on the battery is connected to a contact point on the panel, while the switch goes in the rest of the hook-up, as indicated. There is one interesting point here which must be noticed. If the switch arm is so wide, or the contact points so close together that the end of the blade touches two posts at the same time, the cell between these two posts will be short circuited. In other words, if the switch is kept in

this position for more than a few minutes, the cell will be ruined and it may be necessary to purchase a new battery. To overcome this it would be a wise stunt to insert an extra switch point in between the five regular ones; the extra ones will not be connected with anything. These will simply act as spacers and be dead.

Figure 2—The tapped B-battery with control of voltage utilizing a switch arm.

As an added instrument, an A battery potentiometer may be used. This gives extra-fine adjustment of the tube; but it really is not necessary except in radio-frequency amplifiers. The correct method is shown in the accompanying sketches. The ends of the winding go directly across the 6-volt battery, while the arm is the common terminal for the input and output circuits of the tube. It will be noticed that the potentiometer, notwithstanding its high resistance, acts as a drain on the battery in order to do away with this loss and to have the instrument connected only when the set is used. It is suggested that a double-throw switch be used. This cuts off the filament as well the potentiometer at the same time.

The use of this device is simple. Before making any other adjustments, set the arm at the middle of the winding. Now proceed to experiment with the values of the other elements of the tube control, get what you think are the correct amounts, and then listen in. While doing so, move the potentiometer arm slowly either way until signal strength is secured. Remember that the action of the B battery may be compared to a pump. When it forms part of a circuit, it pumps electrons out of its negative terminal and into its positive terminal. The flow of electrons is around the circuit. This flow is a current of electricity. It may be measured by an ammeter placed at any convenient point in the circuit.

Yes, Radio Is Quite au fait!

(C. Underwood & Underwood, N. Y.)

The leading hotels of America now have their radio rooms, and guests hear the finest concerts. This photograph was taken in the "Radio Room" of the Greenbrier Hotel, White Sulphur Springs, West Virginia. Harry Sadenwater, radio engineer of the General Electric Company, New York, is announcing the next number on the program; Mrs. Charles F. Thompson of Washington, D. C., and Mrs. A. N. Fay of Pittsburgh listening in.

National Radio Week Has Been Set for December 23 to 30 (inclusive)

Major J. Andrew White Appointed Chairman of Executive Committee. Preparations and Programs to Be Planned At Once

NATIONAL RADIO WEEK has been definitely set to take place from December 23 to December 30 (inclusive). This was decided unanimously at the meeting of radio magazine editors, publishers, and representatives of the radio trade, the National Radio Board of Trade, and the American Radio Exposition, held at the Bankers Club, New York, on October 24.

So the idea suggested by Radio World, in its issue of October 21, becomes an assured fact. Radio World is pleased—happy beyond expression—that National Radio Week is not to be confined to its efforts alone, but is to be—as it should be—a big, broad, national affair in which every radioist—man, woman and child—may not only take active part but feel that he is an integral factor in its success.

The meeting at the Bankers Club—preceded by a luncheon at which the greatest optimism in the future of radio was expressed—was presided over by L. S. Byers. Among those present were: Frank Hitchcock, Postmaster General under President Roosevelt; H. Gernsback, Editor of "Radio News"; Lawrence A. Nixon, managing editor, "Radio Dealer"; Amedee J. Casey, "American Radio Journal"; John Gillette, "Electrical Merchandising"; Austin C. Lescarbours, "Scientific American"; Mr. Crosby, "Modulator"; Mr. MacAttamany, "Radio Retailer and Jobber"; Mr. Wardrop, "Radio Merchandising"; Arthur H. Lynch, "Radio Broadcast"; Kenneth B. Warner, "Q. S. T."; Mr. Henderson, "Talking Machine Journal"; Mr. Robertsen, "Talking Machine World"; Mr. Miller, "Radio Digest"; Mr. Callahan, "Radio Topics"; Kenneth Payne, "Popular Science Monthly"; Roland Burke Hennessey, editor, "Radio World"; Walter Gordon Clark, Harold Bolster, George Brokaw Compton, Chester D. Humphrey, and Messrs. Davis and Hunter, of the National Radio Chamber of Commerce.

Major White was appointed chairman of an executive committee to take charge of the details of preparations for National Radio Week.

A supplementary committee of one hundred will be appointed. The members of this committee will be published in the next issue of Radio World.

So National Radio Week takes definite shape and form! The week (December 23 to 30 inclusive) was chosen not only because this is to be actually "A Radio Christmas," but because it will give wider scope for broadcasting and for amateur transmitting. It is a week when the younger element—whose interest in radio is as keen as that of the grown-ups—

will have ample time to join in the many festivities that will be planned and carried out.

National Radio Week, remember, is not a local affair. It extends to every hamlet in the country. Every fan and amateur is expected to take part—and particularly, for the future of radio, to interest his friends in the new science; to bring strangers into the evergrowing radio field.

Watch Radio World for National Radio Week news. And let us hear from you if you have any practical suggestions that will help to make the week a history-making one.

"What would you do to make National Radio Week a success?"

Let us have your answer to this question.

Letters commending National Radio Week continue to pour into the office of RADIO WORLD. Here are just a few of the many received. They show the trend of opinion:

O. H. Caldwell, editor of "Electrical Merchandising," will give his publication's aid:

Congratulations on your plan for a National Radio Week! "Electrical Merchandising" will publish an announcement in its next issue regarding this idea. It opens up interesting opportunities. Please keep us in touch with any developments that take place in your program.

Major General George O. Squier, Chief Signal Officer, U. S. A., will cooperate:

I believe it is a very good idea. Anything that will help to stimulate an interest in the radio art and bring about a wider diffusion of the knowledge of the art is worthy of every effort. I have no specific suggestion to offer; but I shall be glad, in a general way, to cooperate in any way I can to help towards the success of this enterprise.

Major J. D. Felsenheld, Radio editor, "The Jerseyman," Morristown, N. J., is in line:

This department will be glad to cooperate with you to the fullest extent in putting over a big National Radio Week. If you can go through with it, the stadium stunt will suffer a total eclipse. Let us know if we can be of any assistance.

Glenn Howell, Lieutenant-Commander United States Navy, says N. R. W. should accomplish results:

Your suggestion for National Radio Week is believed to be very appropriate and, no doubt, should accomplish results which would be beneficial to the radio business and science as a whole. Should it be desirable for the Navy to take an active part in such a celebration, it would be necessary to consult the Secretary of the Navy. You have my best wishes for the success of this venture.

Be a National Radio Week Booster

Last-Minute Radio News

WIRED RADIO is the latest corporation to file its charter in Wilmington, Delaware. Its purpose is to develop systems. The capital stock is \$10,000,000. The holding company is the Corporation Trust Company of America.

Recent modification of the rigid laws governing the installation of radio telephone and telegraph stations have made possible the installation of radio broadcasting, according to Vice-Consul Edwin B. Montgomery of Montevideo. Applications are now pending which, if granted, should mean the opening of a splendid market for radiotelephone receiving apparatus in Uruguay.

Application for Government sanction to establish a radiotelephone system has been made by the Daido Electric Power Company, of Nagoya, Japan, according to advices received by the Department of Commerce. The company proposes to operate this system primarily for its own convenience in connecting the various stations with its electric light and power system, but its

use may be extended to the general public. As at present planned the wireless system will start from Okuwa in Nagano Prefecture on the Central Japan Railway Line, from which point communication will be established through Nagoya and as far as Osaka, a distance of about 150 miles. American firms interested in the possibilities of supplying equipment may obtain the name of the purchasing agents for the Daido Company in the United States from the Electrical Equipment Division, Bureau of Foreign and Domestic Commerce.

More About the Telephone Mystery

Editor, RADIO WORLD:

In your issue No. 28, dated October 7, I read the letter from Albert Lundberg, Fairdale, North Dakota, in regard to re-

ceiving telephone messages from a nearby telephone line.

I had a similar experience. Sometime back, a friend and myself, while experimenting with standard regenerative receiver-circuits, put in a short ground line house-telephone system so that we could compare notes on our work. By accident we discovered that we could talk to each other through the transmitter of the house phones and receive through the radiophones. Further experiments convinced us that a standard ground-telephone system would radiate sufficient induction to be received by a radio receiver (regenerative) as far as 50 feet from the receiving instrument. This experience may afford some one a chance to do some work along this line.—R. O. Nemeier, 497 Winona Avenue, Pasadena, Calif.

Radio-Equipped Polar Weather-Stations Sought

By Washington R. Service

WITH the perfection of radio communication, great progress has been made in another science which is, perhaps, of equal value to the world at large, particularly the seafaring and agricultural nations. Meteorology has advanced with leaps and bounds during the past few years. Due chiefly to radio, the outposts of meteorological knowledge have been pushed far afield into distant and unpopulated wilds where, previously, lack of communication has withheld local weather conditions from the world.

Last winter, an American engineer, Hagbard D. I. Ekerold, spent months on a barren rock 400 miles north of Iceland, in the Arctic Ocean, as the leader of a meteorological expedition backed by the Bergen Geophysical Institute. His observations were believed so important to the rest of the world that an observatory was established by the Norwegian Government at Jan Mayn, this lonely spot of rock in the Arctic sea.

This new northern observatory has a wireless station, so that weather observations may be broadcast as fast as noted. Scientists hold that this, the station farthest north, is the beginning of a new epoch in the history of science, admitting that credit is due to radio.

Meteorology is fast becoming an international study, for the storms and weather of one country soon affects the situation in another, and, to-day, the immense area covering the whole of Europe, Northern Africa, and the Near East, as well as the United States and Canada, is combed with great care by weather observers and their reports received at central points, abstracted and broadcast by radio daily from Washington, Paris, and a few substations. Thus it has become possible for meteorologists to obtain within twelve hours of the taking of the observations, a representative meteorological situation over the greater part of the Northern Hemisphere, extending from the Pacific Coast of America to Russia and Egypt.

Professor Bjerknes, of Norway, who has done much to advance our knowledge of cyclones forming in the temperate zones, holds that weather conditions there depend chiefly on the conflict between two streams of air—a cold current flowing southward from the north Polar regions and a warm current drifting northward from equatorial sources already well known. These air streams, he believes, meet along a wavering front in the temperate zone, and in their intermingling create those mysterious swirls in the

atmosphere which are called cyclones. To study these possibilities, he desires to establish a chain of radio-equipped observation stations near the Pole, from the records of which the tracks followed by the Polar current southward and the centers of conflict with the warm currents may be definitely determined. Such a series of circumpolar meteorological posts will have more than theoretical importance when regular forecasts for the North Atlantic are required in connection with daily air flights between Europe and America, he says.

This Observatory at Jan Mayn, which transmits by radio observations six times daily, constitutes the first link in the chain with Spitzbergen. Mr. Ekerold has made a proposition to England, the United States, and Canada, to establish a third link in the Arctic chain at Baffin Island, on Davis Strait near Western Greenland, over a thousand miles from Jan Mayn, Iceland, and Newfoundland. This third radio station would aid materially in studying the weather in the Far North which is practically unknown. From these stations observations aiding in establishing forecasts for the Northern hemisphere and the North Atlantic trade and air routes would emanate.

(Cartoon by Lawrence B. Hinckley)

TOO DEEP FOR DAD

Young Amateur: "Say, father, if I hook up a five ten-thousandth-microfarad condenser on the antenna circuit, and a variometer in the plate circuit of the electron-relay, do you think my set will oscillate?"

19 More Broadcasters Are Licensed

TWELVE licenses were issued by the Department of Commerce to 360-meter broadcasters and seven to Class B Stations operating on 400 meters, as follows:

Limited Commercial or Broadcasting Stations for 360 Meters, Licensed Between October 14 and 21, 1922.

WMAY—Kingshighway, Presbyterian Church, St. Louis.

WNAT—Lennig Bros. Co., Philadelphia.

WNAH—Manhattan Radio Supply Co., Manhattan, Kansas.

WOAV—Pennsylvania National Guard, Erie, Pa.

WMAW—Wahpeton Electric Co., Wahpeton, N. D.

WTAW—Agricultural & Mechanical College of Texas, College Station, Texas.

WPAA—Anderson & Webster Electric Co., Waco, Nebraska.

WNAJ—Benson Co., Chicago.

WMAN—Broad Street Baptist Church, Columbus, O.

KFBV—Clarence O. Ford, Colorado Springs, Colo.

WMAX—K. & K. Radio Supply Co., Ann Arbor, Mich.

WSAV—Clifford W. Vick, Radio Construction Co., Houston, Texas.

Class B Station to Operate on Wave Lengths of 400 Meters, Licensed Between October 14 and 21, 1922.

WDAF—Kansas City Star, Kansas City, Mo.

WOC—Palmer School of Chiropractic, Davenport, Iowa.

WHB—Sweeney School Co., Kansas City, Mo.

KDKA—Westinghouse Electric & Manufacturing Co., East Pittsburgh.

WSB—Atlanta Journal Co., Atlanta, Ga.

WFI—Strawbridge & Clothier, Philadelphia, Pa.

WBAP—Wortham-Carter Publishing Co., The Star Telegram, Fort Worth, Texas.

"My short experience with radio convinces me that future generations have something to live for."

—Sir Thomas Lipton.

Keep Your Clocks Right by Radio

By Carl H. Butman

WASHINGTON, D. C. — Through Naval Radio broadcasts, it is now possible to set clocks and watches to standard time twice daily. At noon, and at 10 o'clock every night, the Naval radio stations at Arlington, Annapolis and Key West transmit radio signals, indicating the exact time for the 75th meridian or standard eastern time.

The actual time is kept at and sent from the Naval Observatory in Washington, the source of standard time for the territory east of the Rocky Mountains, the chronometer and time office at the Naval Station at Mare Island, California, serving the western territory and ships off the Pacific Coast.

In a deep, even-temperature vault at the Naval Observatory three Riefler clocks keep sidereal, or star time, and although they are not quite correct, it doesn't matter. They are checked by the observation of certain stars as they cross the meridian, and their exact error and rates of error calculated. Having obtained the exact Washington sidereal time, a correction for the difference in longitude of Washington and the 75th meridian—which is 8 minutes and about 15 seconds—is made to secure Eastern Standard time. This is kept on two transmitting clocks, one of which sends out the time signal to the three radio transmitting-stations by means of a relay.

Previously to sending the time signals, the sending clock is checked with one of the standard Riefler clocks by comparing their ticks which are recorded on a chronograph, wavy pen lines indicating the separate ticks. These are measured by a finely divided scale and compared. Determining the error, the sending clock is speeded up or slowed electrically until its ticks correspond exactly with the standard clock.

The ticks of the transmitting clock are sent to the three transmitting stations by closing a switch at the observatory, but they are broadcast by radio from the three stations. Five minutes is required to send a complete time-signal, starting at 11:55 and running to noon, and from 9:55 to 10 p. m. The time signals consist of telegraphic dashes every second except the 29 of each minute, the 55th to 59th seconds of the first four minutes, and the 50th to 59th seconds inclusive of the last

(C. Kael & Herbert)

Radio fans wonder how WJZ, Newark, New Jersey, retransmits the Arlington, Virginia, time signals every day. The time signals are received from Arlington on this heterodyne receiver, after which they go through the amplifiers to the aerials. This heterodyne receiver operates on from 250 to 2500 meters. The photograph shows Raymond F. Guy, well known to radio audiences as "O.G.N.," retransmitting the Arlington time signals.

minute before the hour. Each of these blanks is caused by a missing tooth on an otherwise complete gear-wheel. Following the 59th second of the last minute, there is a long dash commencing at the beginning of the new hour. Listen in for NAA on 2650 meters and set your clocks then.

By means of a radio receiving set at the observatory the message of ticks may be caught and recorded

on a chronograph for comparison with the sending clock's record to determine the loss in transmission. It averages about .09 of a second. The time signals sent from Annapolis on a wave length of 16,900 meters have been heard in Australia, while in the Antipodes time signals have been heard coming around the world both ways. With a receiving set it is now no excuse to say "my clock was wrong."

Better Radio for Infantry Units

SIGNAL Corps radio engineers are perfecting a better field-radio set for army infantry units. The present spark set, SCR 105, developed during the World War, has become practically obsolete and continuous-wave sets are desired.

A board of Signal Corps officers, which met at Camp Vail, New Jersey, recently, has recommended that surplus sets such as SCR 79-A, 127 or 130 be issued to infantry regiments for training purposes until continuous-wave sets can be developed and distributed to replace the old 105s. Recently the continuous-wave sets were adopted for all Army radio communication.

The old 150 sets are quenched-spark sets used for transmitting and receiving between headquarters, usually not more than five miles apart, but if an amplifier was employed by receiving stations it was useful up to about thirteen miles.

The SCR 79-A, one of the sets recommended by the board as a temporary

substitute, is a vacuum-tube set designed for transmitting undamped waves and for receiving either damped or undamped signals. The transmitter delivers about ten watts to the antenna, and the messages will carry about twenty miles on waves between 500 to 1100 meters. This set was designed for use at command posts, or at headquarters, where transportation is available.

Details of the new sets are not completed, but it is understood that they have a range of about ten miles, and will be used between regiments and brigade headquarters.

Radio Don'ts

Don't attach ends of antenna to power or telephone poles.

Don't connect a radio set direct to the electric light circuit.

Don't forget that tickler coils are not used with crystal detector sets.

The Radio Primer

*For Thousands of Beginners Who
Are Coming into Radio Circles*

Weekly A B C of Radio Facts and Principles Fully and Tersely Explained

By Lynn Brooks

What is a variable condenser?

A VARIABLE condenser consists of a number of semicircular metal plates arranged in two sets. One set is stationary; the other may be moved on a pivot so that both enter between the stationary plates but without touching them. All the stationary plates are connected and, likewise, the rotating plates. The plates may be of aluminum, brass, or any other metal that retains its shape.

* * *

What is the function of the variable condenser?

The variable condenser supplies an electrical quantity known as capacity. Radio circuits are made up of inductance and capacity. Tuning coils supply much of the inductance while condensers are depended on to supply the capacity. Perhaps a clearer idea of capacity would be gathered if a condenser were to be considered as a miniature storage-battery which catches and holds the minute electrical impulses until there are sufficient to make an impression on the head phones.

* * *

How does a variable condenser store up these impulses?

Strange as it may seem, it is not the metal plates in a condenser that hold the impulses, but rather the air between the plates. The impulses come in from the aerial and are transferred to the detector circuit by simple tuner, loose coupler, variometer, or vario-coupler. The sounds are made up of little trains

of waves. These trains come into the metal plates of the condenser and cannot jump from one set of plates to the other. Thwarted, they are still able to strain or twist the air between the plates. This action is the same as when a piece of soft rubber is twisted in one's hands. So long as the pressure is maintained, the twist will remain; but if one hand is removed, the rubber returns to its former shape and size. In the condenser, the waves strain the air and the air holds the strain until it has stood all it possibly can. Then it "back fires," to use a common term.

* * *

Are other than variable condensers used in radiophone sets?

Yes. There are grid condensers, fixed condensers and the by-pass condenser. These are used in receiving sets.

* * *

What is the grid condenser?

When a train of waves enters from the aerial through the secondary of the loose coupler or vario-coupler, the grid is affected with an alternation of positive and negative waves. As previously described, the flow of electrons from the filament is helped when the grid is positive, and hindered when the grid is negative.

* * *

What is a grid condenser made of?

A few square inches of tin foil separated by a good grade of waxed paper, both materials being folded several times to conserve space.

Radio Terms That Puzzle Beginners

NEW radio fans seem to have difficulty in understanding many of the technical terms connected with the art. In many cases, incorrect definitions are published. These frequently cause confusion, and poor results when applied to the operation of radio instruments. A few of the more important terms are herewith defined:

Crystal Set.—This type of receiver derives its name from the form of detector used with it. A detector of this sort depends for its rectifying qualities on a little crystal

of one of the number of crystals, such as galena, silicon, carborundum and others. The disadvantage of the crystal is the range which it offers. It is satisfactory in a range from 15 to 20 miles. Its advantage is due to the fact that its upkeep is low—comparatively inexpensive. For short-distance work, it gives satisfaction.

Regenerative Set.—This is the vacuum-tube set; for crystals cannot regenerate. The regenerative action depends on feeding part of the current flowing through the plate circuit back into the grid cir-

cuit, thus increasing the grid current and, likewise, the current in the phones. This feed-back is accomplished by either tuning the plate circuit, or by using a tickler coil or a coupler condenser.

Lines of Force.—Those invisible streams of magnetism that surround a coil of wire, such as tuning coil, loose coupler, or vario-coupler. It is these lines of force that transfer the electrical energy from the primary coil of a tuning device to the secondary coil. That these lines actually exist can be proved easily by laying a piece of paper on which fine iron filings have been strewn. The filings will assume positions along curved lines which lead

How lines of force act in a radio loose-coupler

How the lines of force would affect iron filings if the metal particles were spread on a sheet of paper over a bar magnet.

from one end of the magnetized strip to the other. Although there is no metal around tuning coils except the copper wire—which is nonmagnetic—these lines of force exist. They pass out of the individual turns of the coil down through the center and around to the other side.

Non-magnetic.—The term applied to some common metals which are not attracted, or repulsed, by a magnet. Copper, brass, carbon, and gold are nonmagnetic metals.

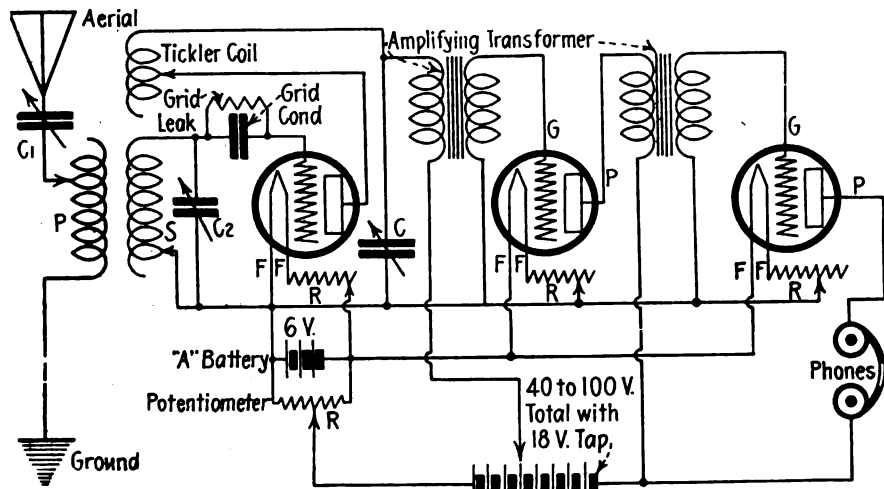

Radio Notes

SOMETIMES it is difficult to find a sensitive spot on your crystal. Try the following plan: Take a discarded crystal, and pulverize it, but not very finely. Put some of this inside a metal casing and screw it into the cup of your detector. You will be surprised to note how quickly you can find a good spot.

The receiver is capable of all sorts of refinement. The best way to perfect one is not to hurry the job. Some amateurs take months to build their sets; but when the sets are finished, they are real ones. *The secret of radio construction is patience.* Even after the set is completed it is well to try making a few changes in the wiring provided this seems necessary.

Receiver for Amplifying Weak Signals

By Horace Beers

Complete schematic diagram of a detector and two-stage amplifier as described in the accompanying article.

THE regenerative type of receiver has come into very common use in the reception of both radiophone and radiotelegraph communication, and the added increase in strength of signals makes it possible for this type of receiver to catch the very weak signals from exceedingly long distances whereas with other types of receivers amplifying transformers are employed for loud signals.

It is my idea that we employ the amplifying transformers in connection with a receiver of the regenerative type. This would in turn give very satis-

factory results, especially to those interested in listening to the broadcasting stations. The accompanying illustrates a detector and a two-stage amplifier of the regenerative type. This form of receiver is unusually selective in its tuning, and requires critical adjustment in order to get the best results. The amplifier acts as a magnifier of the signals received by the detector. With each stage of amplification, the incoming signals are magnified many times.

With this regenerative receiver, distant stations may be brought in and the fan will experience for the first time

the complete satisfying thrill of hearing a faint voice announce, "This is broadcasting station WOC, Davenport, Iowa," or "this is 'Atlanta Journal' station WSB." True enough, the signals will be weak and they'll fade in and out as is customary with all distant transmitters, but they are *there!*

Most every listener is gifted with patience beyond the ordinary; for it requires considerable practice before the operator is sufficiently skilled to tune in these faraway stations. It is usually necessary to become somewhat of a "night" owl as these long-distance stations cannot be picked up with just a turn of the knob. However, until WJZ and WOR "sine off" for the night, the local interference is apt to make such an attempt hopeless.

In using a regeneration set, especially those who are not familiar with oscillation, a rushing sound like that of falling water is heard just at the point where the secondary and primary are tuned to the same wave-length. The broadcasting wave will make known its presence by a squeal, or whistle, the pitch of which may be varied at will. When this is tuned in, the primary circuit should be varied until it is as loud as it possibly can be made, then the plate and secondary circuit-condensers should be readjusted sufficiently to eliminate the whistle and bring in the broadcasting clearly.

Radiomen at WJZ We Hear But Never See

(C. Kadel & Herbert)

THOMAS H. COWAN, "A.C.N."

Mr. Cowan is concert manager at WJZ and one of the pioneer announcers. He has the distinction of having announced the first radio concert ever given and the first World's Series baseball games. He is 25 years old, single, and formerly was connected with the Metropolitan Opera Company.

RAYMOND F. GUY, "O.G.N."

Mr. Guy, who is 24 years old, and married, has been with WJZ since December 1, 1921. He is one of the best known operators in the country—for WJZ, Newark, N. J., is widely heard. The initials are arranged to read, if one wants to know: (O) operator, (G) Guy, (N) Newark. In the instances of Messrs. Cowan and Watt, (A) is for announcer.

JOSEPH L. WATT, "A.W.N."

Mr. Watt is in his 30th year, and married. His particular work is to announce the many literary features sent out by WJZ. When you hear the familiar voice saying, "A. W. N. announces this or that," then you know that Mr. Watt is speaking. His cheery voice has been heard, it is estimated, in almost every State in the Union. He is a pioneer among radio announcers.

How to Learn the Code This Winter

By Ortherus Gordon

RADIO WORLD has suggested since its beginning, that the newcomers in radio learn the Continental Code. That this was appreciated was made evident when it was necessary to republish the code for the benefit of those who were lacking a copy of it and were requesting the editor to supply it. In this article, I suggest the use of a practice outfit for learning code and offer an outfit that may be constructed by the ambitious amateur at very little cost.

If you are the only amateur in your community, owning such a set, you can command the interest of the other radio enthusiasts by inviting them over for code practice. They should bring their headsets, plug in on the buzzer, and take down the messages as you send them from your own home-made key and buzzer. Hide or muffle the buzzer so that its sound is not audible, or put it in the next room, and you will treat your friends to actual receiving conditions combined with a speed they can read and understand.

The outfit I describe is, also, ideal for radio clubs wishing to organize code classes for work during the winter. Only two instruments are needed—a key and buzzer, with a dry cell for operating them. If you own a crystal set, then you already have the buzzer; but since it is desirable to have this practice set mounted on a single board, you may want to build another. Amateurs who own regenerative outfits do not use buzzers as detector tests and, therefore, should follow the plans as they appear in this article.

While definite instructions are given, it is understood that the dimensions and other features of the drawings are not rigid by any means.

The key shown is a serviceable and yet simple affair. For its lever use a 5-inch piece of 1/4-inch solid-brass rod. This rod is drilled as

Figure 2. The buzzer. Made according to these dimensions, it will have a high, pleasant pitch.

shown in the drawing—all taps being the useful 8/32. The knob is made of wood or hard rubber.

If the amateur wants a good-looking knob, consider the tops of ink-bottle corks. I mean the two or four-ounce bottles and not the office size.

The spring is made of spring brass and may be cut to suitable dimensions. The uprights are made of brass plate or of wood, the only requirement being that they afford a rigid fulcrum for the lever. The fulcrum pin is a brass rod passed through the lever at right angles and fitted snugly into holes in the uprights.

A convenient feature of this key is the use of battery binding posts for contacts. Take the nut of any dry-cell binding post and saw it in half. This will give you the upper and lower parts of the contact. Fasten the lower part to the base of the

key and the upper to the lever, as shown, and then file them flat so that a perfect contact is made when the key is pressed. Only the principal dimensions are given.

The buzzer—full plans of which are shown in Figure 2—may be explained as consisting of three parts, each part to be made separately and put together last. They are the coil, the vibrator, and the thumbscrew.

The coil has a soft-iron core. In this buzzer it is 2 inches long and 1/4-inch in diameter. This core may be either a solid piece of iron or a bundle of thin iron wires; but they must be soft iron. If steel is used, it becomes permanently magnetized and defeats the principle on which the buzzer works. The core is held firm by two wooden ends, 1 inch square and 1/4 inch thick. It is embedded in the after end, as shown, but protrudes through the forward end 1/16 of an inch. When it is rigidly set up in these supports, wind it with six or seven layers of No. 18 or 20 cotton-covered copper wire. Bring both ends out free. If you wish, give the coil a coat of shellac or cover with tape for appearance sake.

The vibrator is a strip of copper or brass 2 5/8 inches long by 3/8-inch wide. You may use spring brass if you wish, but it is not necessary. One end of the vibrator is made fast to the standard while the other end is wrapped with a piece of tin. This tin is placed directly in line with the center line of the core, as shown in the sketch. This is necessary because an electromagnet does not attract copper or brass.

The thumbscrew hardly needs explanation. It is merely an 8/32 screw fitted into a brass standard, or support, and placed so that it is just to the side of the tin plate on the vibrator and touching it.

The connections are as follows: One end of the coil goes directly to

Complete schematic diagram, giving the necessary dimensions for the construction of a transmitting key. For the lever use a 5-inch piece of 1/4-inch solid-brass rod. The knob may be of wood or hard rubber. The spring is of spring brass, and the uprights of brass plate or wood. The fulcrum rod is a large brass pin. Battery binding-posts are used for contact. Read the accompanying article carefully for further detailed instructions which the amateur builder should follow closely.

Conductive Amplifying Receiver Picks Up Long Distances

DR. FRANCIS LEROY SATTERLEE, noted X-ray specialist who is now devoting himself to radio research at his laboratories, Flushing, New York, is shown in the accompanying photograph with his "inductive amplifier," a non-regenerative radio-receiver working on an entirely new principle. With it he has reached unusual distances, having heard from Ontario, as far south as Louisville, Kentucky, and over a sweep from Memphis to Denver. The apparatus has the effect of radio-frequency amplification without employing radio-frequency bulbs and transformers, the receiver using only one bulb for radio-frequency detection. The signals are then amplified by two or more steps of audio frequency in the usual manner. This is the same set

By Herbert K. Dale

that interested Major-General George O. Squier, Chief Signal Officer, U. S. A., who said he would give fifteen minutes to see a test of this receiver, but actually gave three hours.

The novelty in Dr. Satterlee's set is the arrangement of the inductances. He uses three flat spiral-wound coils which look a great deal like a small talking-machine record. Two operate with a "butterfly" motion. The third moves through an arc between the

other two, similar to a bookmark slipped between pages of a book. Rough tuning is accomplished by a variable condenser, and thence finer tuning by the variation of the positions of the three coils.

Extreme ease of manipulation and freedom from distortion are features of this set. With a 125-foot aerial, Dr. Satterlee hears distant points.

The large set on left of the lower illustration shows the original set made by him, while the small set on the extreme right is the present-day model embodying the same principles.

(Continued from preceding page)
the binding post. The other end goes to the vibrator, while the second binding post is connected with the thumbscrew. Figure 3 shows the hook-up for the key, buzzer, and dry cell—together with the head-pieces as they should be connected in order to hear the buzz of the instrument loud and clear. There is no limit to the number of headphones that may be connected to the buzzer outfit in this manner. In fact, in radio schools where the

Figure 3. Hook-up for buzzer set with two or more headphones attached for code practice.

teaching of code is an important part of radio work, the headphone extension is run down the center of a long table, with jacks at every chair, so that at times as many as one hundred students are listening in on what the instructor is sending.

These instruments have been designed separately; but you can put them both on the same base and save binding posts. Such a set is invaluable to the amateur who is eager to learn code.

Both photographs (c) Kadel & Herbert.

Radiograms

Latest Important News of Radio Garnered from the World Over, and Reduced to Short Wave-Lengths for the Busy Reader.

THE possibilities of the radiotelephone as a newsgathering agency were demonstrated in a dramatic manner, recently, when "The Inquirer" was the first newspaper in Philadelphia to receive word of the disastrous fire which swept the business district of Atlanta, Georgia. Through Edwin A. Hoban, a member of "The Inquirer's" local staff, a radio enthusiast, the news came into "The Inquirer" office even before the first flash from the Associated Press reached Philadelphia. The information came from station WSB, operated by the Atlanta "Journal," and located in that newspaper's building. The news, announced by the speaking voice instead of by the more conventional medium of the telegraph instrument, came floating through the air, a distance of approximately 760 miles.

The Bureau of Mines of the Department of the Interior is seriously considering the problem of equipping mines with radio apparatus for use in the event of accident. The stringing of telephone wires is impracticable, but officials state that it would be fairly simple to equip certain distant rooms, or chambers, with crystal receiving sets so that rescue parties could communicate with imprisoned miners. The real problem is to find a simple and portable transmitting set by which the miners could communi-

cate with the mouth of the mine of the outside world in the event of being injured in or imprisoned after an accident.

* * *

Several types of speaking movies, based on the principles of radio will be tried out on the New York public in the next few months. The most serious competition will be probably between the General Electric Company, which is reported to be perfecting its talking film in a studio on Long Island, and Dr. Lee de Forest, who is working with motion-picture actors and directors at a studio near this city. The General Electric talking film and the de Forest invention both consist of films in which the voice and other sounds are photographed at the edge of the motion-picture film itself. The photographed sound waves are reproduced in each case with the aid of the photographic cell. Those who have heard the Lee de Forest phono film and the General Electric talking film say they have both reached a high degree of perfection and reproduce the human voice.

* * *

Rear Admiral W. H. Bullard, U. S. N., who was in charge of the navy radio service during the world war, says that five powerful radio stations would soon be in operation in China with sufficient energy to communicate direct with San Francisco. Admiral Bullard says that radio will not supplant, but would supplement, cable lines, telegraph and telephone.

* * *

Corkscrew Radio May Serve to Pick Up Rum Runners

(C. Fotograms, N. Y.)

Don't throw away that corkscrew—even if the Volstead Act is in force. There still is a good reason for keeping it around the house. It can be improvised into a real radio outfit, that may do everything a radio outfit should do. This photograph shows Jack Riley with his corkscrew radio. It is not a complete outfit, but it will serve to pick up warnings for the rum fleets. Two receivers are attached to the device, which is guaranteed to pick up all radio messages within a fifteen-mile circle. It is only necessary to attach it to a light plug or charged wire in order to hear music or bed-time stories as you drink.

Great Britain is just beginning to regulate radio broadcasting. The British scheme is to have all broadcasting done by a single organization which will be sanctioned by the government, operated by manufacturers of receiving sets, and financed by both. Present plans call for the establishment of eight stations in the British Isles, at London, Manchester, Birmingham, Glasgow, Cardiff, Plymouth, Newcastle and Aberdeen.

* * *

The Mercantile Trust Company of San Francisco has established a broadcast station on Telegraph Hill, and will broadcast financial, industrial and general business information throughout the territory west of the Rocky Mountains.

* * *

"Ariograms" is the name given to United States Department of Agriculture radio reports.

* * *

The Los Angeles "Evening Herald" is broadcasting lessons in code fifteen minutes every week day. This is the first step in the way of definite instruction by radio. The University of California extension division, Berkeley, is supplying a correspondence course in elementary radio. California is keeping to the fore in radio enterprise.

* * *

Dr. Nicholas Murray Butler, President of Columbia University, believes that the motion picture and the radio-telephone are going to become invaluable in the educational work of the future. He lays stress, however, on the necessity for the right material being filmed or broadcast.

* * *

Here are three extraordinary transmission records. Two western correspondents. E. J. Conkelman, Enterprise, Oregon; and E. M. Bacigalupi, Hillyard, Washington, reported successful reception of the WGY concert of September 26 and, in both cases, their reports checked up accurately with the WGY station log. Hillyard is seven and one-half miles northeast of Spokane and 2,200 miles from Schenectady. The distance has been bettered by WGY but never during the early fall. Mr. Bacigalupi reported that his reception was made on detector alone with a Grebe Cr-9 and no amplification. His time of reception was 6:15 to 6:30 p. m., Pacific time.

On September 29, Private G. G. Westfall, operator at Fort Randolph, Canal Zone, Panama, 2,250 miles from Schenectady, reported that he had on that date heard WGY in spite of a powerful arc set which operates twenty miles away at the Balboa station. Mr. Westfall is operator at the United States Army station. His call is WNCI. This reception is the more remarkable because of the heavy static which prevails in the warmer climate of the Isthmus of Panama.

Still another unusual reception is reported by J. C. Grindell, manager of the Rectifier Department of the Valley Electric Company, St. Louis. Mr. Grindell reports that he heard WGY's program Friday evening, September 29, on a home-made crystal set without amplification. His aerial, he explained, is one wire 65 feet long and 30 feet high. St. Louis is approximately 875 miles from Schenectady.

Radio and the Woman By Crystal D. Tector

I CALLED at the office of RADIO WORLD, the other day, to have a little chat with the editors about National Radio Week. Friend Husband advised me not to do so. He told me that the editors are usually so busy they become ferocious and devour people on sight—that they imagine that every woman who enters a sanctum wants to sell a poem on spring—that women talk editors to death, and all that sort of chatter. Well, I didn't heed F. H.'s warning.

* * *

I must admit that editors are just like any other type of human beings and will stand perfectly still without being hitched. They don't bite, or even bark; in fact, they seem to have all the necessary elements of kindness that one expects to find in ordinary men. When I reached home and told this to Friend Husband, he simply laughed and snickeringly asked if I hadn't got in the wrong pew! Fancy! I found the editors of RADIO WORLD not only willing to talk but very (*We modestly delete the rest of Miss Detector's flattering comment. She is entitled to her opinions; but the power of the blue pencil must be preserved—The editors.*)

* * *

Well, I left their offices convinced that National Radio Week will be about the biggest thing in the United States this winter. The date—December 23 up to and including the 30th—could not be more satisfactory, for we will have two Saturdays during the time of the year when everyone will be on the alert for fun of some sort. And as so many of us are looking to radio to provide something new in the way of pleasure, it does seem that the prevailing slogan: "This is a radio Christmas," is most appropriate.

* * *

Mother was telling me that she remembers when the automobile first came into popularity. There was such a week celebrated in her home town. It wasn't a big national affair such as our National Radio Week will be; but a purely local occasion. Although there had only been about two automobiles in the town up to the time "Automobile Week" was announced, everybody got so het up over the event, ma says, there were nearly a hundred cars in the parade—and some of them were the worst looking home-made affairs imaginable. It seems that everybody who was able produced a car for that occasion, and some folks even made their own. Ma says that she will always remember "Automobile Week" at home because an old-maid sister whom the folks thought would never marry found a willing beau.

* * *

From the stories she tells, the spirit of the people in making that week a success must have been something wonderful. And if such a spirit existed in one little town a quarter of a century ago, what must it amount to in this huge nation to-day? Personally, I am full to the brim with energy to make National Radio Week a success. I'm going to be the best little booster of them all. And I'm asking every one of my big family of readers to get right in and help me enthuse women all over the land.

* * *

I want you to send me suggestions. For instance: we should have an emblem, or a pin, or a hat band, or something else that can be worn that week. Who will be the first to suggest some attractive design or monogram? Who will be the first to send in an appropriate slogan? Who can think of something absolutely original for that week? Who will organize a committee to get the shopkeepers busy with window displays?

* * *

My first suggestion is that radio parties be made a bright particular feature of the occasion. They will blend most attractively with the Christmas festivities—particularly as so

many churches are interested in broadcasting and so many ministers are broadcasting their sermons. Why, I am told that thousands of poor people and cripples who never have a chance to attend church now thank God that radio can bring words of sacred cheer to them in their loneliness. Can't someone suggest something unusual for these unfortunates during National Radio Week?

* * *

And for the radio parties we will want all sorts of new radio dishes—dishes that are tasty and easy to make. Girls, haven't some of you a recipe for a radio pie? Can't some one think of a radio cake?—or a radio salad? If you will send in something along the line of edibles, I will have Friend Husband make up a radio drink. I'll promise that it will be quite in keeping with all the prevailing laws and that the recipe will be published in plenty of time for all who wish to use it.

* * *

Here in New York the spirit of National Radio Week is already apparent among radio fans. You hear it talked about already, and many plans are being made. But we want it to move westward with the sun. We want it to get so deep under the skin of every fan that he will not be content to enjoy it by himself or in the company of other fans, but will bring strangers into the vortex of things. One of its principal objects is to bring new fans into the fold. And if every radioist is responsible for at least one genuine beginner, radio will receive an impetus that will help all of us.

* * *

Friend Husband told me at dinner, the other day, that there is a fan in the office—remember, not an amateur but a fan. F. H. says that he asked the man, in a casual sort of way, if he really cared for radio. "Care for it!" the man flared up. "Why, I wouldn't be without it." Then he went on to tell of all the wonderful pleasures that his set had brought him. This man is just one of many—but there are millions more like him who do not know what a truly satisfying pleasure maker radio really is. We want these unknowns in the ranks of radio and we are going to get as many of them as possible in the ranks during the big week.

* * *

Now, don't think I am preaching or asking you to do missionary work. Far from it. We who know radio—we pioneers—want to share it with those who do not know. Why, for months I heard F. H. bawl out the man next door because he would not go to the ball games—and F. H. knows batting averages better than I know how to tune in KDKA. Finally the neighbor reluctantly consented to go with F. H. Last season you couldn't keep Mr. Neighbor away from the Polo Grounds with chains. That is the way it will be with thousands who don't know, to-day, whether radio is a science or a door mat.

* * *

I have given up largely of my space, this week, to National Radio Week. But I feel its great importance and I realize that it is going to be one big occasion. I know, too, that much depends on the women of radio to make it a success; because they are nearer to the little ones than the men are. And we all know that it was our boys who really made radio possible—who ignited its first impulse. Think what a combination of radio and Christmas mean to them!

* * *

Let me hear from you all. Start something in your town. Get the spirit. As our editors say: "Be a National Radio Week booster!" I will keep in touch with you regarding all my plans—but you must help to swing this great radio event into one of the most national joy festivals this big bustling country of ours ever knew.

How One of Our Hook-ups Worked

Editor, RADIO WORLD: In regard to the circuit on page 19 of RADIO WORLD (No. 30, dated October 21) issue, I tried it with one small change and brought in San Antonio, Texas, very clearly and fairly loud, using a one-step amplifier. The change made was the use of a variometer in place of the DL-50.

I was greatly surprised by the amount of regeneration obtainable and the ease with which regeneration was controlled by the condenser which would not appear to be in the plate circuit at all.

In the near future, I expect to try several long-wave hookups (1,500 to 30,000 meters) using a single coil, in the hope of finding one which will tune fairly close and give good regeneration with the use of DL coils. I shall certainly try this one with larger coils,

although I am afraid that the size of the condenser will limit the wave-length range to some extent.—L. J. Coleman, Sioux City, Iowa.

(The hook-up referred to by Mr. Coleman was sent to RADIO WORLD by Mr. W. Miller, Southern Methodist University, Dallas, Texas.—The editor.)

(Above) This is the mysterious "Black Box" of Thomas A. Edison, photographed for the first time. Through this mysterious device he discovered what he termed "etheric force," and which is, in reality, the wireless spark of today as perfected by Marconi. Ether is an hypothetical medium supposed to fill all known space, even those portions occupied by fluids and solids. The functions assigned to ether, such as the transmission of transverse waves with the velocity of light and the production, when under certain strains or subjected to certain motions—of all the phenomena due to electric and magnetic fields of force—indicate properties unlike those of any known form of matter.

Edison Invents Transmitter That Will Eliminate Unnecessary Noises

No. 1,425,183. Patented, August 8, 1922. Patentee: Thomas A. Edison, East Orange, N. J.

My invention," declares Mr. Edison in a description published by the United States Patent Office, "relates to transmitters, and more particularly to microphone transmitters wherein the desired variations in current are produced by variations in electrical resistance caused by varying the pressure upon a quantity of granular conductive material, such as carbon, which is disposed between electrodes in the circuit carrying the current, preferably in a somewhat loose state, the requisite changes in pressure being effected between the electrodes and the granular material by a diaphragm, or other means, to be set into vibration by sound waves such as the human voice."

Practically all microphone transmitters of this type such as are now used are seriously and adversely affected by phenomena extraneous to the sounds they are designed to transmit, such, for example, as shocks, jars, vibrations, concussions, etc. These phenomena often

it impossible to understand or even detect the sounds which the microphone is intended to transmit.

The principal object of Mr. Edison's invention is to produce a microphone transmitter which will be extremely sensitive to very weak as well as to loud sounds and at the same time to substantially eliminate or prevent the production of extraneous sounds, making it possible to employ powerful amplifying devices, such as the audion, with the transmitter.

Operating Vacuum - Tube Circuits

No. 1,426,755. Patented, August 22, 1922. Patentees Robert C. Mathes, New York City, and Harry S. Read, East Orange, N. J.

THE invention on which Messrs. Mathes and Read have received letters patent, relates to vacuum-tube circuits, more particularly to multistage amplifier-circuits in which vacuum tubes are employed in the various stages.

It is well known that a vacuum tube of the three-electrode type will reproduce in amplified form in its output circuit impulses impressed upon its input terminals, and that the amplified impulses may be impressed on the input terminals of other tubes to give any desired degree of amplification. When such a multistage amplifier is employed to amplify low frequency impulses, it is generally preferable to have a direct coupling instead of an inductive coupling between stages in order that the low fre-

create such relative movement of the conductive granules disposed between the electrodes of the microphone transmitter as to produce extraneous or foreign sounds, loud enough when amplified to practically obliterate and render

New Signal Receiving System

No. 1,430,533. Patented, October 3, 1922. Patentee: Burke Bradbury, Schenectady, N. Y.

MR. BRADBURY'S invention is to provide a simple and efficient means for providing an audible indication of signals transmitted by means of radio-frequency continuous currents. The receiving station is provided with a source of audio frequency current which is associated with an electron discharge device and a detector in such a way that when no signaling currents are impressed upon the system there will be no ap-

Schematic diagram of Mr. Bradbury's system.

preciable flow of audio frequency current in the detector circuit. When, however, a radio frequency signaling current is impressed upon the system this signaling current is modulated by means of the audio frequency source and the modulated radio frequency signaling current is transmitted to the detector circuit where it is rectified and the rectified current is used to produce the desired audible indication.

Will Help Voltage

No. 1,430,067. Patented, October 3, 1922. Patentee: William C. White, Schenectady, N. Y.

IT has been discovered that the current which will flow through an electron-discharge device comprising an incandescent cathode and an anode enclosed in a highly evacuated envelope will, between certain limits, vary approximately as the 3/2 power of the applied voltage. In other words, the apparent resistance of such a device varies with the voltage applied to it. In some cases, this characteristic is objectionable; for example, when such a device is included in a measuring circuit which comprises other resistance. In such a case the relation between current and voltage in the circuit will be a complex one and a calibration will be necessary to determine this relation.

The object of Mr. White's invention is to overcome this disadvantage by constructing and arranging an electron-

Figure 2 shows the current-voltage characteristics of an ordinary high-vacuum electron discharge device.

discharge device in such a way that the current will vary directly as the applied voltage between certain well defined limits.

Answers to Readers

1. How far could you hear with the hook-up you have on page 7, RADIO WORLD, No. 27, dated September 30, using an aerial of four wires, each eighty feet long?

2. What size fixed-condenser do you recommend on the stopping condenser and condenser before the grid of the third tube?

3. What kind and size tubes are recommended for all three shown?

4. The lead from B battery to 2-circuit jack is about 22 volts. Am I correct?

5. To make a 45-volt B battery may I connect two 22-volt batteries in series?

6. Would the addition of my honeycomb coils help any?

7. Are the two transformers the same size?

8. Will a potentiometer help?

9. What size is the grid condenser and leak?

10. What rheostats are best—the wire type or the carbon type?—F. Bruhns, Oakland, Cal.

1. Everything depends on the way a set is constructed, also the locality, erection of antenna, etc. No exact figures can be given, but there is no reason why considerable distance cannot be received.

2. Usually about .00025 mfd., but this may be omitted from this particular place in the circuit.

3. The first tube is that of a UV-200 detector tube; the next two are the UV-201 amplifying tubes. Be sure to see that the detector tube is used in the first socket.

4. The B-battery voltage on the first tube is about 22 volts.

5. Yes. By connecting two 22½-volt B batteries in series with each other you are able to secure the necessary 45 volts.

6. No. They will not help the circuit in any manner.

7. The two transformers used are the same in size.

8. A potentiometer is of no use with this particular circuit.

9. The grid leak is of 2 megohms and the grid condenser of about .00025 mfd. capacity.

10. This all depends on the radioman who is building the set. Some prefer the wire rheostats, while others like the carbon. A vernier on the detector tube will be of great value.

I have a receiver using duo-lateral coils, and believe I have the wrong hook-up. Note my diagram and let me know what error I have made.—Gustav Altrack, Manchester, Pa.

Hook-up requested by Mr. Gustav Altrack, Manchester, Pa.

The accompanying diagram is the correct method by which you should wire your set. Follow each and every connection carefully and you will get the desired result.

I am building a regenerative receiver with two variometers and a vario-coupler. Can

a dry-cell tube be used with as good results?—Vincent Delapotteries, Wichita, Wis.

Certainly. Use the same circuit, merely connecting a single dry-cell to the A battery terminals.

Will you publish a diagram of a single-tube regenerative set employing three honeycomb coils?—Fred Loveland, Niagara Falls, N. Y.

Diagram requested by Mr. Fred Loveland, Niagara Falls, N. Y.

Herewith is a schematic diagram of a three-coil regenerative circuit employing one of the coils as tickler: P is for primary, S for secondary, and T for tickler coil.

May I run my aerial from a pole to and through the gable of my house, a total distance of 100 feet, and then bring my lead from center of aerial?—Harry Alexander, Staten Island, N. Y.

Leave your aerial an inverted L. Don't run it through the house. We advise you to experiment with it for results, but the outside aerial still holds the record for long-distance reception.

Please publish a hook-up of a regenerative circuit using three tubes, used with variometers and vario-coupler.—Kenneth H. Jones, London Mills, Ill.

A hook-up of this circuit was published in RADIO WORLD, No. 27, dated September 30.

What is wrong with my set? The diagram is enclosed. The aerial is 100 feet long with a 70-foot lead-in. I am using a crystal detector.—Matthew Rasmussen, Syracuse, New York.

Your diagram is wrong. Connect aerial to the switch arm and the ground to the other. Then connect one side of the detector to one switch arm and one side of the phones to the other. Now join together the remaining posts and detector. The phones should then be shunted by the phone condenser.

I have an aerial plug, tuning coil, ground clamp, crystal detector, variometer, phones, and variable condenser. What broadcasting station should I receive with this set?—William Bruns, Boston.

Unless you have an unusual location or live within a mile or two of some broadcasting station, you are doomed to disappointment with the antenna plug. The lighting system makes a fairly good aerial for vacuum-tube sets, though for crystal sets it is practically ruined out.

Wave Meter for Amateur Operators

How to Construct the Device Which Enables You to Adjust Your Set and Comply with the Law

Prepared by the United States Bureau of Standards Experts

THE construction of a portable short-wave radio wave-meter for use of amateur transmitting stations is fully explained in the following article which was carefully prepared by the Bureau of Standards of the United States Department of Commerce. The device is for measuring the frequency or length of radio waves.

According to the Bureau of Standards, amateur radio stations in the United States at present are required by law, when transmitting, to use wave lengths not exceeding 200 meters, and, therefore, it is important that amateur operators should have a wave meter available so that they may adjust their sets to comply with the law. The device should be adapted to measure short wave lengths, such as 200 meters as well as other short lengths such as 300 and 485 meters now used for radiotelephone broadcasting.

The Radiotelephony Conference which met in Washington in February, 1922, recommended narrow bands of waves for particular services, some bands being only 10 meters wide. Stations which must work within such narrow wave bands must be provided with well-designed wave meters if they are to comply with the requirements of the law, and the design of a portable short-wave meter is a matter of importance, according to Bureau of Standards experts.—The Editor.

Figure 1. Arrangement of the wave-meter box and assembled units.

A WAVE METER is a device for measuring the frequency, or length, of radio waves. Radio waves always travel with the same velocity. If the frequency is known, the wave length is also known. Amateur radio stations in the United States at present are required by law, when transmitting to use wave lengths not exceeding 200 meters. It is important, therefore, that amateur operators should have a wave meter available so that they may adjust their transmitting sets to comply with the law, and it is necessary that this wave meter should be adapted to measure short wave-lengths such as 200 meters. Other comparatively short wave-lengths, such as 360 and 485 meters, are now used for radiotelephone broadcasting, and it is important to have a wave meter which can measure these wave lengths. The Radiotelephony Conference which met in Washington, in February, recommended narrow bands of waves for particular services, some bands being only 10 meters wide. Stations which must work within such narrow bands must be provided with well-designed wave meters if they are to comply with the requirements of the law. The design of a portable short-wave meter is, therefore, a matter of importance. It is the purpose of this article to point out the most important considerations in the design of such a wave-meter, and to describe the construction of a wave-meter suitable for the measurement of frequencies from about 3,000 kilocycles per second to 530 kilocycles per second (wave lengths from 100 to 570 meters).

The parts of a wave meter are, usually, a variable condenser, a fixed inductance-coil, and a device to indicate current flow. The condenser will first be considered.

It will be well at the start to eliminate certain large classes of Condensers unfit for use in wave meter circuits. Variable condensers employing other dielectrics than air, and condensers whose capacities are varied by a screw to change the distance between plates, however serviceable they may be for furnishing a variable capacity, will not in general retain their calibration and are untrustworthy for use in a wave meter. This elimination leaves only air condensers whose capacity is varied by changing the overlapping area of parallel plates—the usual type of variable condenser.

All condensers of this type can by no means be used in wave meters. A condenser to be used in a wave meter should have fairly heavy plates rigidly held together with ample tie-rods and nuts, spacing washers of large diameter and sufficient thickness, adequate conical bearings, and, preferably, unimpeded rotation through 360 degrees of arc. Particu-

lars in which variable condensers commonly fail to meet these and other requirements are: too thin plates, spring-supported bearings, extremely close spacing of plates, vertical or lateral play of the shaft in its bearings, contacts made by brushes wiping on movable parts, stops which in arresting the rotating plates shift them out of line, shifting scales or indices, and faulty workmanship which allows short-circuiting of the condenser at some settings. In general, anything that allows a capacity change without a change in scale reading or a change in reading without a capacity change destroys the usefulness of a condenser for wave meter purposes. Some method of shielding is desirable to eliminate any change of condenser capacity owing to movements of surrounding bodies. The shield usually is a grounded metal case placed around the condenser.

Regarding the inductance coils: The requirements of a wave meter coil are: (1) that its inductance be such that with the condenser used the desired range of wave frequency can be covered. (2) that its effective resistance and effective capacity be low; (3) that its inductance, resistance, and capacity all be constant.

The first requirement, which has to do with the range of wave frequencies, will first be considered. It is well to restrict the part of the condenser scale used for frequency measurements to the sector between 15 degrees and 170 degrees on a scale graduated in degrees, or between the eighth division and ninety-fifth division on a scale graduated in hundredths. Since capacity at 170 degrees or 95 hundredths will almost always be more than six times the capacity at 15 degrees or 8 hundredths, the frequency obtained with any one coil at the lower end of this region will be not less than about 2 1/4 times the frequency obtained with the same coil at the upper end. This will make it possible, with one coil, to cover the range from 3000 to 1200 kilocycles per second (100 to 250 meters) and with a second coil to cover the range from 1330 to 530 kilocycles per second (from 225 to 570 meters).

Range of Wave Frequencies

The following table gives the number of turns required for two single-layer inductance coils which will cover, approximately, the stated ranges with each of the maximum capacities indicated in the table. It will be noted that the size of the wire and the spacing between turns are not specified. The inductance is nearly independent of the size of wire used, and the spacing is controlled by the number of turns and the length of the inductance coil, both of which are given. The length of the coil, as indicated, is the length of the actual winding, not the length of the supporting core.

Single-Layer Inductance Coils for Short-Wave Portable Wave Meter.

Coil 1.—Range 3000-1200 kilocycles per second (100-250 meters). Diameter, 10 cm. (4 inches); length of winding, 2.5 cm. (1 inch).

Maximum capacity of condenser	No. of turns
0.0005 microfarad	16
0.0007 microfarad	13
0.0010 microfarad	11

Coil 2.—Range 1330-530 kilocycles per second (225-570 meters). Diameter, 10 cm. (4 inches); length of winding, 5 cm. (2 inches).

Maximum capacity of condenser	No. of turns
0.0005 microfarad	42
0.0007 microfarad	35
0.0010 microfarad	30

The second requirement stated for the coil is that the effective resistance and the effective capacity be low. Low resistance is desirable in order to secure sharper indication of resonance. The practice of surrounding an inductance coil with quantities of miscellaneous insulating material is undesirable in any

Figure 3. Schematic details of wave-meter coil. Turn page sideways when reading.

radio circuit and is especially to be avoided in the case of wave meter coils. Imperfect insulating materials so used increase not only the effective capacity but also the effective resistance of the coil. This does not mean that all types of manufactured insulating materials are unsuitable for use in frames for wave meter coils. Probably, however, the best form on which to wind the coil of a wave meter like that here described is a hollow spool of thoroughly dry wood lightly varnished with an extra grade of insulating varnish. The use of shellac is not considered advisable under any circumstances. The use of wood having even a comparatively small moisture-content may seriously affect the accuracy of the wave meter. Properly selected wood is chosen in preference to manufactured insulating materials, glass, or pasteboard. Many available manufactured insulating materials largely increase both the resistance and the capacity of the coil. While the electrical properties of glass make it well suited for a form, it presents too great mechanical difficulties. Pasteboard is not rigid enough and should not be used under any circumstances. The wire used may be solid copper double cotton covered, No. 24 B & S, or larger. The wire should be lightly varnished with a single coat of an extra grade of insulating varnish. Further insulation merely increases the effective resistance and capacity of the coil without compensating advantages. The resistance frequently can be considerably reduced by the use of the braided high-frequency cable.

That Armstrong Circuit

So much interest has been displayed in the special article, "TESTED INVENTION OF MAJOR ARMSTRONG AMPLIFIERS SET 100,000 TIMES" by John Kent, that appeared in RADIO WORLD No. 13, dated June 24, 1922, the publisher decided to put aside a number of copies for those who were not able to get this issue when published. Copies will be sent, postpaid, on receipt of 15c. or send in your subscription, \$3.00, for one year (12 issues), \$3.00 six months or \$1.50 three months, and subscription will be started with the issue containing the article about Major Armstrong's Amplifier.—RADIO WORLD, 1498 Broadway, New York.

Subscribe direct or through your news dealer. \$6.00 a year, \$3.00 six months, \$1.50 three months. Radio World, 1493 Broadway, N. Y. C.

(Continued from preceding page)

Care must be taken, however, in using the high-frequency conductor to see that all the strands are continuous and well insulated from one another, and that every strand is joined at the terminals of the coil. If imperfect insulation exists between adjacent strands, these high-resistance contacts may cause a considerable increase in the power losses. Broken strands seriously increase both the effective capacity and the resistance of the coil. The strands may be tested for continuity by dipping one end of the cable in mercury and joining the separate strands at the other end successively to a buzzer or voltmeter joined to a battery, the circuit being closed through the mercury contact. The enamel may be removed from the ends of the separate strands by carefully heating the end of the wire cable to a red heat and dipping it in alcohol. This procedure makes the strands more fragile and consequently particular care must be exercised to avoid breaking them.

A single-layer coil has generally a lower effective capacity than a multilayer coil of the same inductance and radius. This, together with the greater precision with which specifications can be furnished for winding single-layer coils, was the reason for choosing this type of coil in the table already given. Since appreciable effective capacities exist when there are parts of the circuit near each other which have comparatively large areas and which are at different potentials, it follows that the leads from the coil to the condenser should not be long or close together. An additional reason for having the leads short is found in the third requirement previously stated for a wave meter coil, namely, that the inductance, capacity, and resistance of the coil, including its leads, be kept constant. Long

Figure 2. The wave-meter circuit.

leads are apt to be flexible; and flexible leads, long or short, introduce possibilities of change in inductance, capacity and resistance which can not be compensated for by any slight advantage they may give in convenience of handling.

The best leads are rigid metal terminals soldered to the ends of the wire and screwed to the wooden core. The position of the coil should be such that the plane of the turns of the coil is perpendicular to the condenser plates if the condenser is unshielded. This is to prevent the induced current in the coil from itself inducing eddy currents in the condenser plates. Since it is almost always desired for convenience in coupling to have the plane of the coil vertical and the condenser plates horizontal, this matter will usually take care of itself. A very important precaution in giving the coil permanent characteristics is to draw all the turns tight and so fasten them that, with ordinary care in handling, they will not shift.

The coils may be attached to binding posts on the wave meter, so that they may be conveniently connected or removed. Various other methods of attaching may also be used.

The third part of the wave meter is the device which shows current flow, and thus indicates resonance. If a crystal detector and telephone receivers are used, only the one-point (unilateral) connection should be employed; that is, the detector and telephone receivers are joined in a closed circuit, and one point of this circuit is joined to one terminal of the coil. This arrangement is sufficiently sensitive and makes the calibration of the wave meter fairly independent of the position of the telephone leads, at least so long as they are not closely drawn across some part of the wave meter or wrapped around it. A more precise indicating device is a thermogalvanometer or a radio-frequency milliammeter.

Available types of thermocouple instruments are usually found more satisfactory than the ordinary expansion type of hot-wire instrument, because they respond more quickly to changes of current. The instrument should give full scale deflection with a current of about .1 ampere. It should be able to stand a considerable overload. It is generally inserted directly in the wave meter circuit, sometimes with a shunt to keep low the resistance of the circuit. It is important to note that the presence of the instrument will probably modify the capacity, inductance and resistance of the circuit, so that the wave meter should be calibrated with the same instrument in the cir-

Save on 1.50 Detectors | Save on 3.00 Amplifiers

Repairing all detectors and amplifiers using a single tungsten filament such as the following listed tubes: Marconi, Moonland, DeForest, A. P. Shrover, Radio, Radiotone UV-200, UV-201, Conestogham C-200, C-201.
Detectors and Amplifiers repaired for \$2.50.
The repaired tubes, we warrant, will give you the same absolute satisfaction that you would expect to receive from new tubes.
We are now in a position to give guarantee for prompt deliveries with satisfactory results. A reasonable trial will confirm our reliability.

Radio Goods that Stand the Test

Manufacturers, send a sample of your goods to our Technical Editor, Fred. Charles Ehlert, 8008 Pleasant Street, Queens, Long Island, N. Y. It will be carefully tested and returned. If your goods satisfy our experts, RADIO WORLD'S endorsement will be published in our merchandise department without charge or obligation of any kind on your part. This is a free service on the part of RADIO WORLD, calling for no expense whatsoever on the part of the manufacturer, except the sending of a sample of his goods.

A Well-Constructed Variable Condenser

Manufactured by Caldbeck Tool & Manufacturing Co., Des Moines, Iowa.

A WELL-DESIGNED and well-constructed 23-plate variable condenser, the capacity of which was found to be, approximately, .0005 mfd. The construction of this condenser is as follows: All plates are of the best-grade even-gauge hard aluminum, and are laid out mathematically correct so that the area increases with the square of the angle.

The edges are so cut as to prevent burrs. This keeps down the leakage when using it with C-W transmitters. All of the insulating bushings used in this condenser are treated in boiling beeswax to prevent the absorption of moisture. This treatment also makes the bushings self-lubricating.

The condenser is nicely finished and when used with a set comprises a satisfactory receiver ready for panel mounting. It was tested out in all sets and found to stand up under all conditions.

"Make Your Own Variometer"

Racine Radio Parts Co., Racine, Wis.

A "Make Your Own Variometer" has been tested out after being assembled. By the instructions and illustrations that accompany it, it will be found easy and interesting to assemble. The parts come complete. In one hook-up, it was placed in the aerial circuit of an oscillating receiver and found to have a wave-length range from 150 to 450 meters. It behaved well, without showing signs of being noisy. The rotor and stator are wound with cotton-covered magnet wire. In construction and appearance it is very attractive, and neatly finished for panel use.

New Firms and Corporations

(The firms and corporations mentioned in these columns can be reached by communicating with the attorneys, whose addresses are given whenever possible.)

Heard at the Radio Counter

A Conversation Between Customer and Radio Clerk
(Part III)

"FINISHING up my set the other night, I noticed that the signals came in weak at times and, at other times, the set went absolutely dead. With a move or adjustment of the condenser, or plate variometer, everything was 'jake.' Must need a rheostat—don't you think?"

"I believe your trouble lies right there."

"Do you think a vernier rheostat would help the set?"

"Absolutely."

"How do vernier rheostats come, and how do they operate?"

"Well, there are the different makes and types; and anyone will supply the need of vernier control."

"All right, then; I'll take one and try it out to-night. And, by the way, will I also need a vernier on my amplifiers?"

"No—not at all. Just use one on the tube in your detector circuit."

"Very well, then. I hope this will keep the signals in at all times—especially when giving a concert to my friends who are on the verge of buying sets."

"If you are in any more trouble, Mr. Customer, with that set of yours, come in and fire away. That's what we're here for. We are here to give you advice as well as sell you merchandise."

"Thank you. Will see you shortly."

Foreign Orders for American Business Men

Lynn W. Meekins, New England district manager of the United States Bureau of Foreign and Domestic Commerce, broadcasting foreign inquiries from the Amrad Station of the American Radio and Research Corporation at Medford Hillside, Massachusetts. This is the first office of the Department of Commerce to use the Radio and the first station to send out foreign trade information. "A firm in Switzerland wants to buy thousands of electric light sockets," says radio. The next morning the bureau's office in Boston receives scores of applications from firms throughout New England for the name and address of the Swiss importer. This is the highest speed that foreign trade promotion has yet attained.

Million - Watt Vacuum Tube May Send Human Voice Across Atlantic

A MILLION-WATT vacuum tube has been developed in the General Electric research laboratory, Schenectady, New York, by J. H. Payne, Jr., says "The World," New York. The huge capacity tube is a magnetron, involving the principle of magnetic control as developed by Dr. Albert W. Hull of the laboratory.

The tube is expected to be of much importance both in radio work and long-distance power transmission. Its output is about forty amperes at 25,000 volts, and serves as a rectifier to change alternating to direct current, and also to change direct to alternating current of any frequency or to convert low frequency alternating current to high frequency.

It is thought that one tube will be sufficient to carry radiotelephone signals across the Atlantic. This tube consists essentially of a water-cooled cylindrical anode 30 inches long and 1 3/4 inches in diameter. In the axis of the anode is a tungsten filament four-tenths of an inch in diameter and 22 inches long. This filament is excited by a current of 1,800 amperes at 10,000 cycles, the filament excitation requiring about 20 kilowatts.

The magneto field produced by this large heating current is sufficient to "cut off" the electrical current from the cathode of the anode during a portion of each half cycle of the current passing through the cathode; this action taking the place of that of the grid in the three-electrode tube. The electron current to the cathode is thus interrupted 20,-000 times per second.

By the use of properly tuned circuits this can be used for the production of high-frequency power radio or any other purpose.

Don't expect to get loud signals with a crystal detector set while using an indoor antenna.

Non-liquid Storage A- and B-Batteries

THERE are now on the market A- and B-storage radiobats which incorporate a number of revolutionary new features of considerable interest to every radio fan. Both A and B types of these new principle-batteries contain a solid electrolyte which makes them absolutely nonspill. This feature will be appreciated by every radioist who has ever spilled acid from his battery on his carpet or clothes.

Another interesting feature is the total absence of separators which reduces internal resistance to a minimum. The radiobat grid (the metal mesh into which is pressed the "active material," forming the "plate") has a double reinforced construction. This construction adds from 25 to 30 per cent. more actual metal per square inch. The plate is, consequently, just that much more rugged and does not buckle. This reinforced strength plus the solid electrolyte makes the use of separators unnecessary. Due to the fact however, that the secondary reinforcing mesh in the grid does not come to the surface of the plate, there is actually more active surface per square inch of plate area. In the case of the radiobat A, this results in a battery from 25 to 30 per cent. smaller and, consequently, easier to handle than any other A battery of equal rating.

The radiobat storage B is even more unusual and interesting. It is compact—only four inches square by seven inches long—scarcely larger than a large-size dry-cell B. It has no glass jars to break, no liquid to leak. The most notable feature is its utter noiselessness of operation.

It substitutes the steady, sustained voltage characteristic of a storage battery in place of the irregular constantly dropping voltage of a dry cell, thus eliminating all hissing and crackling noises with which all radio operators are familiar. Changing voltage in the plate circuit is the direct cause of most tube noises and most of what is blamed on static. Sustained voltage does away with this and results in a marvelously clear true-tone reproduction of each word and note.

The Radiobat Storage B is economical as well. It is easily rechargeable at home from either AC or DC and outlasts its value in dry cell Bs on each home charge.

Honeycomb Coils Suggested for Usual Wave Length Ranges

I Want a Radio Worker In Each Community To Work For Me

My work fits in nicely for those men and women who have spare hours or full time at home and wish to earn from \$5.00 to \$40.00 weekly, depending on time you devote to it. It is not radio work, but I believe anyone energetic enough to interest themselves in Radio will make an excellent "TANGLEY BRANCH MANAGER," to operate a branch for us in their home. Pleasant, easy work, no canvassing, immediate profits. No experience or special talents necessary. We furnish complete outfit, train you for the work, and assist you in building up a business you will be proud of. Don't wait until another grasps this offer, write today for literature, and make your spare hours earn.

71 West Broadway New York City

cuit as will be used in measuring frequencies. An inexpensive indicating device and one which is satisfactory when the power output of the generating circuit is large enough, is a miniature lamp, such as a flashlight lamp, inserted directly in the wave meter circuit. To avoid any possibility of changing the calibration of the wave meter, the lamp should not be changed if it can be avoided. If it must be changed, it should be replaced by one of identically the same kind. The sensitiveness of this device can be greatly increased by having a dry cell and a rheostat in parallel with the lamp in the wave meter circuit. By ad-

justing the rheostat until the temperature of the lamp filament is raised almost to the point of illumination, it is possible to have the lamp lighted by induced currents much smaller than would otherwise be required. However, changes in the battery and rheostat will be likely to change the characteristics of the circuit and hence the calibration of the wave meter. This device, therefore, should be used with caution.

The wave meter may be excited by impact, that is by a source of highly damped waves having only a very few waves in a train. The wave meter can then be used as a source of damped waves to determine the frequency to which a receiving set is tuned. The buzzer, in series with the battery, is connected across the condenser terminals, completing its circuit—when the contact is closed—through the inductance coil of the wave meter. Not more than four volts should be used to operate the buzzer. The buzzer will add to the capacity of the circuit, thereby decreasing its frequency. This decrease will be especially noticeable at the lower part of the condenser scale, where it may amount to several per cent. of the frequency. It can be reduced by having short, widely spaced leads to battery and buzzer. If the wave meter is equipped with both a buzzer and an ammeter, or current-square meter, the ammeter must be so connected in the circuit that the current from the buzzer battery cannot pass through the ammeter. If this is not done the ammeter or current-square meter may be burned out by the current caused to pass through it by the buzzer battery.

The assembling of the parts of the wave meter must be such that each part is rigidly joined to the rest of the circuit. Mounting in a box is as good a means to this end as any from the standpoint of rigidity and is superior to any in portability and in the protection afforded to the parts. A convenient box mounting is shown in Figure 1.

The over all dimensions are left to the constructor since the size of the component parts will vary. The box should be substantially constructed so that it will stand considerable handling. The component parts are all mounted on a panel of rigid electrical insulating material which will not absorb moisture. This panel is, in turn, secured to the supporting box. It is possible to use a panel of thoroughly dried and seasoned hard wood thoroughly varnished with an extra grade of insulating varnish.

Figure 1 shows one possible distribution of the component parts. Attention should be given to the convenience of operation and advantageous wiring of the circuit to keep distributed capacities at a low value. The most advantageous arrangement of the instruments on the panel will depend in part on the particular instruments used, and the constructor should work out the best arrangement in each case.

Figure 2 gives a circuit diagram showing the connections as they should appear underneath the panel. These connections should be made of No. 12 solid copper wire soldered into lugs. Where bending is necessary, sharp right angle bends are used. If it is desired to make a short-wave portable receiving set, terminals for antenna and ground connections can be supplied without decreasing the value as a wave meter in any way, provided suitable care is used in handling the instrument. A wave meter should be handled more carefully than an ordinary receiving set. If it is desired to shield the wave meter, a copper, or brass, sheet may be permanently fixed on the under side of the panel and spaces cut in it to allow for the terminals and supports of the various units. There should be at least 1/8 of an inch clearance for the terminals.

Figure 3 gives the dimensions and construction of the inductance coils.

The forms are turned in a lathe from thoroughly seasoned wood. Several coats of extra grade insulating varnish applied to this form will be desirable in keeping low the absorption of moisture. The proper number of turns of the correct size of wire is wound in a single layer in the recess provided for this purpose. A light coat of extra grade insulating varnish is applied to the wire to keep it in place and to prevent moisture from changing the distributed capacity of the coil. The terminals of the inductance coil are brought out through the wood form and soldered to the supporting brass terminals. The wood supports holding the coil form to the brass supports should be of brass rather than a magnetic material.

It is desirable that the box be provided with a protecting cover and a carrying handle.

After the wave meter has been constructed it must be calibrated. Consideration has been given to the transmission of standard wave length signals from laboratories equipped with precision measuring apparatus. This would make it possible to determine accurately several points on the calibration curve of a wave meter without sending it to a standardizing laboratory. The carrier waves of some radio-telephone broadcasting stations may be adjusted to some particular wave, such as 360 meters, and one point on a wave length calibration can thus be determined. A wave meter transported for standardization should be packed in a wooden box large enough to give room for three inches of excelsior.

Radio Services Are Deeply Appreciated

RELIGIOUS services at 10:30 a. m. and 4:30 p. m. every Sunday have become a regular feature of the broadcasting program of WGY, the General Electric Company's radio broadcasting station at Schenectady, N. Y. The morning service, in every case, will consist of the entire service of one of Schenectady's churches, which will be connected with the transmitting equipment of the big radio station by telephone wire. The afternoon or vesper service will be conducted in the station studio.

The expansion of WGY's program to include Sunday has come as a result of thousands of letters from radio listeners within the station's transmitting radius. A great many of the letters were from aged people, too feeble longer to go to their churches but earnest in their desire for spiritual uplift. Among the letters were also a great many pathetic appeals from invalids, some of whom must spend their life in a single room. To such as these the deep swelling tones of the organ, the singing of hymns, the responsive readings, and the sermon are a real inspiration—a boon that lifts them out of the monotony of their existence and gives them a share in the activities which have failed to touch them.

Another class, and probably the most numerous, that has requested radio church-services are residents of country districts too remote from churches, or of localities where churches are closed because of the scarcity or expense of a regular pastor. In one case, it is known that a little group of neighboring farmers has gathered at the home of one of their number who had a powerful receiving set with loud speaker, and listened in, following the scripture reading in their own Bibles, making the responses in the psalter reading and joining in the congregational singing.

The first service sent out by WGY was from the First Methodist Episcopal Church, the Reverend Philip Frick, pastor. Three microphones were placed in the church, one located near the singers and the organ, the second at the pastor's reading desk, and the third in an anteroom for the announcer. Controlling switches brought any of these three microphones into the circuit.

While wandering from one radiophone to another we often wonder what it is all about—whether anything really matters after all, and, if it does matter, what are we going to do about it. Perhaps we are getting to be a radiofanatic.—"The Sun," New York.

Radio

Inland so deep all roaring waves are still;
So far at sea that dock lights long have died
And there's no sound of any train or mill;
Across the mountains high and deserts wild;
Where arc lights flare, or candles softly glow;
Past harbors where ships lie with canvas furled;
From sunrise to the twilight's afterglow
Man's puny voice is heard around the world.

—Walter Trumbull, in "The Herald," New York.

Although the domestic demand is light, numerous firms in and about Berlin manufacture radio apparatus. Curiously, vacuum tubes are "almost unavailable," says Vice-Consul Davis.

Broadcast Bill's Radiolays

By William E. Douglass

(Copyright, 1922, Westinghouse Electric & Manufacturing Company.)

I'VE been to lots of parties, but the best I've ever seen wuz one we had at our place, in the barn, on Hallowe'en. I had the haymow all fixed up with punkins an' with corn an' them there fancy lanterns; when I's through you would a sworn the place wuz built fer parties. I had apples hung on strings an' some others to be bobbed fer, an' a lot of crazy things. When the folks begun arrivin', I got dressed up in a sheet—one that covered me all over, couldn't even see my feet. Then I met 'em at the doorway 'fore they climbed up in the mow, pointed out how they could get their, givin'

"It don't seem to faze her—boys; I'll tell you, she's a bear."

each a little bow. Abe an' Milly were the last ones, they drove up in their new flivver, an' I guess I musta scared it; when Abe stopped I saw it shivver. Well, us three went up together fer the party had begun. They were workin' on those apples an' in general havin' fun; we had cider an' some doughnuts, an' a lot of things to eat; an' those punkin pies that Min makes, let me tell you, can't be beat. We played a lot of games an' then I walked right out in front an' sez, "Each person present has to do a little stunt. If you can't sing a song, you'll have to hand us out a joke. Abe Jenkins, you kin start it off, then we kin watch your smoke." Well, everything wuz goin' smooth until Rebecca Vance sed if she had some music, she'd put on a ballet dance. Now Becky's eddicated—been away to school a heap, an' she kin do them dances, almost does 'em in her sleep. The stunt that I had planned to pull wuz with my Radio an' I wuz waitin' so I'd be the headline of the show. But, when Rebecca wouldn't do her dance without a tune, I 'lowed as how my act would slip fer I would just as soon pick up some real jazz music so that she could do her bit. I thought that she wuz stallin' an' that she would throw a fit when she found out that I could get the "music in the air." It didn't seem to faze her—boys, I'll tell you she's a bear. The first piece I tuned in wuz "Stumbling," which you've heard before an' so she stumbled in her dance—you ought to heard 'em roar. She'd taken several encores, an' an' we'd all quit clappin' when the chap announced the band would play that tune, "Do it Again."

A Broadcasting Record

WHAT is believed a record-distance for daylight broadcasting was made by WGY, the General Electric Company, broadcasting station, in reporting the recent World Series. Baseball fans in Havana, Cuba, 1500 miles from Schenectady, reported distinct reception of the game of Thursday, October 4.

The series was reported, play by play, by W. O. McGeehan, sporting editor of the New York "Herald." A leased wire carried the story of the game from the press box in the Polo Grounds, New York, to the transmitting apparatus of WGY, 150 miles away. From WGY, the story traveled on Hertzian waves to listeners within hundreds of miles. Many letters and telegrams were received expressing appreciation for the prompt baseball service. Fans were able to follow every play and actually visualize the game.

The following cablegram was received from Havana:

"Havana Life" published a front-page story which in part, states: "The broadcasting of the World Series games by the New York Herald and WGY has made a great hit in Cuba. In was heard distinctly throughout the republic, according to reports received by 'Havana Life.' Our managing editor, Fred M. de Stefano, heard the report from the receiving station of Cecil J. Dale at Marianao, near the Oriental Park Race Track. F. W. Borton, president of the Electrical Equipment Co., of Cuba, leading radio fan, pays a great compliment on the clearness with which the report was received here."

A Radio Newspaper

A PARIS newspaper has ceased to be printed and is published orally. The subscribers meet in a hall and listen to the editors and reporters. The editorial staff has specialists who address the subscribers on topics of the day. So far the experiment has proved profitable. It saves the mechanical cost of publication and the white paper, says "The Globe," New York.

Here is an idea that might be adopted by one of the radio stations. The main cost of a daily newspaper is not the pay of the reporters, copyreaders and editors; but the cost of the mechanical departments and the white paper. By substituting radio broadcasting all the typesetting, stereotyping, and printing-press machinery would be dispensed with. There would be no expensive system of distribution, such as wagons and trucks. The hundreds of tons of white paper could be left to grow into spruce trees in the forest.

This may come some day; but the difficulty at present would be in collecting from the subscribers and in preventing anybody with a receiving apparatus from getting his daily news and editorials without paying for them. The subscribers would also have to go without cartoons and illustrations, unless they installed the more expensive and complicated apparatus recently invented, by means of which pictures can be electrically transmitted.

May—What did Noah do for laughs on his voyage in the ark with no radio to tune in on jokes from ABC and XYZ?

Ray—You recall that he took two of every animal known?

May—Yes.

Ray—Well, the hyenas were the laughing stock of the ark.

—"Topics of the Day" Films.

Fifty-two issues for \$6.00. Sub. Department, Radio World, 1493 Broadway, N. Y. C.

The Assembly \$27.50 Detector and Tuning Unit

A high-grade tube set that costs less than price of parts used. Super-sharp tuning through double circuit and Litz-wound rotor. A real tube set for the price of a good crystal set. MASTER BALDWIN PHONES

AN IMPROVEMENT ON WHAT WAS CONSIDERED THE BEST

Those who know, in the radio world, have always used the Baldwin Phone. It has been ever-present where exacting work was to be done. It was conceded to be eight times more sensitive than any other known phone.

Not satisfied with even such a meritorious article as this, the manufacturers have now produced the Master Baldwin Phone. A 40% improvement in refinement and workmanship. Going still further, they have designed the Clarophone, the most marvellous speaker yet produced. Prices:

Singles, \$9.00 Headset, \$16.00 Clarophone Loud Speaker, \$22.50

THE MOST SENSATIONAL

radio development since the Vacuum Tube. After years of experiment and proof, this genuine fixed Radio detector is now available to amateur and professional operators. Its introduction marks the third GREAT step in the progress of Radio—first the crystal then the vacuum tube and now the wonderful Phonophone. Price, \$9.50, sent postpaid.

Direct or at your dealers.

John Bull's Radio Exchange

WHAT is said to be the first radio-
phone exchange in the world was
recently opened at Croydon, England, the
point from which the air lines to the
European Continent take their departure,
according to Consul Linnell.

The chief use made of this exchange is to connect the serial-traffic controller, who has his headquarters in a control tower at Charing Cross, London, with the pilots of the air express flying between Croydon and the Continent.

This wireless exchange can also connect the phones of the airships and airplanes while in flight with any office at the aerodrome at Croydon, making direct telephone conversation possible.

The pilot of each aerial transport is now required to report his position to the traffic controller every fifteen minutes, so that the progress and position of each plane is known throughout its journey. The controller is of particular value in directing the course of the aircraft in cases of fog, and in giving them special directions for landing.

The Radio Bug

I WAS sitting one day at my office desk,

Writing of boys and men,
When a radio bug crawled out of a crack
And perched on the tip of my pen.

He scratched his neck with a wiry paw
And gazed at my half-writ poem,
Then settled back with a sleepy air
And ohmed an indolent ohm.

"Your room is chilly," said he to me,
As he shivered his aerial wire;
"If I were you I know what I'd do—
I'd build me an ampli-fire."

Then, tipping back 'till the pen point
cracked,
He ohmed again and said,
"I swallowed a couple of codes to-day
Any they gave me a pain in the head."

I asked him about his sister Ann,
And Galena so crystal fair.
"Oh, Gale is tickling the cat," said he,
"And Antenna is up in the air."

"I think that Ann's getting sour because
Of the unripe currents she ate,
For when I come with 'the weather' she
scolds,
'Now, wi-re you in-su-late?'"

He kicked his foot in a drop of ink,
Then slid from my pen with a snap—
Gave a switch to his tail and disappeared
Where the spark had begun to gap.
—Le Roy W. Snell in "The American
Boy."

"If I buy a radio apparatus, is there
any danger of getting a shock?"
"Only when the dealer tells you the
price."

—James Madison's Comedy Service.

NA-ALD DE LUKE V. T. SOCKET

Contact strip of laminated phosphor bronze press firmly against contact pins, regardless of variation in length. No open current Condensite. Practically unbreakable. Special protected slot, with exterior reinforcement. Unaffected by heat of bulbs or soldering iron. All excess metal eliminated, aiding reception. May be used for 5 Watt power tube. Reliable and Beautiful RADIO-A RE-CHARGER

THE RADIO-A is a highly efficient dependable piece of apparatus, absolutely fool-proof, easily attached by simply plugging into ordinary 110 volt lamp socket. In case of current failure, the unit cuts out automatically until current is resumed, without discharging battery.

It is designed expressly for re-charging radio filament batteries, but may be used for automobile or any other storage battery of reasonable size and capacity.

Price, \$18.50

Dealers and Distributors

Here's a Winner! Write us for full particulars.

Simply screw into any 110 volt lamp socket and connect the terminals to your battery. Impossible to hook-up wrong—RADIO-A charges either way.

A compact portable Re-charging Unit that will fully charge a 100 A. H. Battery overnight, for from 5c to 10c, according to prevailing rates.

LAST A LIFETIME

King Electric Mfg. Co., Inc.
1681 FILLMORE AVENUE
BUFFALO, N. Y.

Cavite to Washington, by Radio, in Four Minutes

THE transmission of a routine radio-message from the Naval Station at Cavite, Philippine Islands to Washington, D. C., was accomplished recently by the Naval Communications Service within four minutes. The total distance is 11,500 miles, establishing a new record for long-distance land and transpacific communication.

Ordinarily, with the delay on account of schedules, a message from Cavite to the Navy Department would not be delivered in less than several hours, and sometimes a whole day is required in the transmission, due to relaying and other causes.

Of course, the message was relayed at San Francisco, where it was received from Cavite, but as the radio circuit to Washington was "set up" the message was relayed immediately. Within four minutes after the sixteen-word dispatch left Cavite, it was received on the aerials on top of the Navy Building in Washington and read in the receiving room below. Radio communication is said to be instantaneous, and a signal is instantaneous; but a message is slower due to

the fact that time is required to transmit it, record it, retransmit and again record.

Westward, transpacific radio messages are relayed to Guam and Cavite through Honolulu. Recently through the operation of the Fanning electrical relay at Honolulu, 184 words were automatically relayed to Guam from San Francisco without being transcribed or retransmitted, thus saving considerable time in their dispatch.

Radio Jokes

Jay—How is your new Radio set?
Ray—Great, but my wife is kind of jealous of it!

Jay—Howzzat?
Ray—I have a loud speaker.

—"Topics of the Day" Films.

"The Radiophone has wonderful possibilities."

"Yeah. When they get it perfected we can visit with relatives without having to feed 'em."

Spinkus—Old Henpeck doesn't look as downhearted as he used to.

Spunkus—No, he doesn't have to listen to his wife talk any more. He has a

radio set and wears receivers around the house all the time.

Hearing Atlanta in Des Moines

EDITOR, RADIO WORLD: I noticed in RADIO WORLD (No. 29, dated October 14) that a Des Moines, Iowa, man heard Atlanta, Georgia. We pick up Atlanta every time they are on—and they come in perfectly. We also pick up the Norton Laboratories, Lockport, New York; also Schenectady, New York, and both come in loud and clear—just as natural as if in the same room. Our outfit is only a single detector-bulb regenerative set, but it works fine! —Newby Auto Electric, Milford, Iowa.

Clever Lawyer—Now, if you will let me have some of his love letters—Breach-of-promise Gertie—I haven't any. We both had radio sets.

—"Topics of the Day" Films.

RADIO MAN, eleven years' experience in all sides of the game, capable of constructing, installing, operating broadcasting station of any power, desires permanent connection. Go anywhere. What can you offer? Evans, Momus Pier 48, N. R., N. Y. C.

NEWS AND GOSSIP OF THE STAGE—Send 10c. for specimen copy of NEW YORK STAR, the great illustrated theatrical weekly. \$4.00 year, \$2.00 six months, \$1.00 three months. New York Star Co., 1493 Broadway, N. Y.

ASTONISHING results Rokay Regenerative Hook-up without use of Variometers—variocouplers, switches, taps, etc. ONE SINGLE CONDENSER CONTROL ONLY. The coming receiver. Simpler than a non-regenerative—better than any regenerative we have tested. Hook-up, \$1.00. Money Orders only. Saves you \$10.00 in building your own. With properly wound coils, \$3.50 post paid. Complete receiver parts on wood base with Vacuum Tube, \$8.00. Head set and "B" Battery, \$21.35, Express paid. Rokay Electric Co., Ingomar, Ohio.

HELP WANTED—MALE

EARN \$110 to \$250 Monthly, expenses paid, as Railway Traffic Inspector. Position guaranteed after 3 months' spare time study or money refunded. Excellent opportunities. Write for Free Booklet G-151. Stand. Business Training Inst., Buffalo, N. Y.

DO YOU USE A CRYSTAL DETECTOR? ARE YOU MAKING A CRYSTAL RECEIVER? Increase the efficiency of your crystal detector 1,000 per cent by using a "PT" Ultra-Sensitive Contact. Of special gauge and alloy; makes and holds a quick, ultra-sensitive, stable, adjustment. Endorsed by RADIO WORLD. Using galena, you may pound panel or table without disturbing sensitivity in slightest. Proved practical on ship-board by an oldtime Marconi operator. Using a "PT" Contact on galena, Arlington (NAA) was brought in clear at 3,300 miles (below the Equator); and Arlington came in loud at 2,200 miles (off Dutch Guiana). In both instances, nearby ships using vacuum tubes were unable even to hear NAA. As to stability, Cape May (WCY) was worked over 1,000 miles, sending right through crystal with 2 KW spark, without affecting detector's adjustment. Replace your insensitive unstable spring or catwhisker with a Contact which will hold its adjustment in addition to giving louder signals and music. Indispensable for use in your crystal set, regardless of make. A novice can install. "PT" ULTRA-SENSITIVE DETECTOR CONTACT, with instructions, twenty-five cents, coin or M. O. "PT" CRYSTAL CONTACT CO., Box 1641, Boston 8, Massachusetts.

CASH FOR OLD GOLD, Platinum, Silver, Diamonds, Liberty Bonds, War, Thrift, Unused Postage Stamps, False Teeth, Magneto Points, Jobs, Any Valuables. Mail in today. Cash sent, return mail. Goods returned in ten days if you're not satisfied. OHIO SMELTING CO., 337 Hippodrome Bldg., Cleveland, Ohio.

What Is It?

THE State Music Dealers' Association, of Iowa, met a few days ago and discussed the radio situation, says "The Mail," New York. Whether a radio set is a musical instrument or a scientific commercial device was one of the "big" questions that occupied the attention of the members. The delegates decided that should they class the radio receiver as a musical instrument the various members would lend support in exploiting radio.

This was an odd discussion. That it should occupy the attention of a business-getting organization is one of those things that cannot be understood. In the first place, whether the radio instrument is a musical device or another class of utility, is of no importance. Is the phonograph a musical device? Not essentially, although 95 per cent of the records we have are of a musical nature.

Attention! Fans and Amateurs!

Have you built your own receiver?

Are you experimenting with any particular hook-up?

Are you improving your set?

Are you doing any interesting constructive work in radio?

Why not share this knowledge with your thousands of brother fans who read RADIO WORLD every week?

We want pictures of receiving sets with descriptions of how you overcame some difficulty, or of any additional part or unit that you have added to obtain better results. These are the things that, probably, the other fellow is looking for. Send in your information; pictures or whatever you have done to improve the art.

Remember the beginner is looking for them.

We intend to print in this paper, each week, pictured information and description of value to radio amateurs. If you have found a newer or better way of doing anything, don't keep the secret but tell it to your thousands of brother fans.

Send in a photograph of your set with or without accompanying diagrams and measurement. State whether you figure in the picture yourself, or not, and without any expense whatsoever to you we will make an engraving and publish it. Be sure to write your name and address plainly on photograph.

Send in your picture at once, or if you have not made a set or done anything else in making radio material, tell the boy next door all about this offer.

Since Railroads Took to Radio

ELDERLY Lady: "Can you tell me whether this train plays 'Silver Threads Among the Gold?'"
 Train Caller: "No, ma'am. Take the WJZ local for that number."
 * * *

Beautiful Young Lady: "Can you show me what train to take to hear 'Kiss Me Again,' 'Love's Sweet Song,' 'I'm Crazy Over You?'"
 Train Caller (very embarrassed): "I certainly can. Step this way, please!"
 * * *

Indignant Commercial Traveller: "My train is two hours late again. What-zamatah?"
 Station Master: "It ran out of violin solos at Pittsburgh."
 * * *

Wild Business Man: "Say, looka here! What's the trouble with the 2.15 express?"
 Station Master: "Three hours behind time. It had to stop at Gopher Prairie for a new crystal set."
 * * *

Railroads may shortly announce the suspension of certain trains because of unfavorable static conditions.

Million-Watt Tube Will Radio Voice Across Atlantic

A MILLION-WATT vacuum tube, the most powerful in the world, has just been developed by J. H. Payne, Jr., at the research laboratories of the General Electric Company, Schenectady, New York. Although still in a stage of development, it promises to result in a supertube that will handle unusually large amounts of current.

Its type is the Magnetron class. Its weight is sixty pounds, and it can supply energy equivalent to that required to light 40,000 25-watt incandescent lamps, the current necessary to illuminate 1,500 homes. The tungsten filament, if drawn into a filament of the size used in the home, would supply 175,000 lamps.

The output of this tube is, approximately, forty amperes at a pressure of 250,000 volts. This is about 1,000 kilowatts. The tube serves to act as a rectifier in changing alternating current to direct current. It is also adapted, in an inverted sense, to change direct to alternating current of any frequency, or to convert low-frequency alternating current to high-frequency alternating current.

This new tube is fifty times as powerful as the recent tube invented by Dr. Irving Langmuir, or five times as powerful as the Alexanderson alternator.

(See page 3 for "close-up" and detailed story of this remarkable device.)

Radio Smiles By Arthur G. Shirt

HAVE you read it? The book which tells you how to make a receiving set with a range of 3500 meters out of grandfather's top hat and an old phonograph record?

Where are the novelty banks made in the shape of a radio receiver with a knob that really turns and a tiny bulb that lights up every time you drop in a nickel?

Even in this second winter of the radio craze, there are people who think of laundry starch when the name Armstrong is mentioned.

If every youngster hasn't a home-made radio set constructed by his own hands and at the absurd cost of \$3.64, it's no fault of the magazine articles on the subject.

Try our "Tinpanitone," the new radio diversifier. Each and every unrelated sound magnified and distorted to ten times its original volume! Can be heard for blocks! Splendid opportunity for weary 'phone owners to drive away undesirable visitors! You can't appreciate a good horn until you hear this one!

Have you written your radio book yet?

News head: "De Wolf Hopper broadcasts to thousands that he cannot see." That's nothing. The Sears Roebuck Company has a greater broadcasting radius than any radio station in the country, and daily takes money from thousands it will never see!

Have you heard of the guy who dwells so morbidly on the cost per minute of operating the set when he has company, that his visitors force him to shut the outfit down and talk about it for a while?

Already one-half of the world is plugged in on what the other half is saying.

If people listen-in this winter as they did last, the next generation of flappers is doomed to flat ears and the safe opening wrist twist.

It's coming! A book entitled, "What Every Ardent Suitor Should Know About Radio."

Treat your detector mineral with

KRYSTAL-KLEER

if you want to receive clearly—distinctly—and loud. Try it once and you will never be without it. At your dealers or send fifty cents P. M. O. for a generous sample bottle.

“Close-up” of the Most Important Radio Development of the Hour

By John Kent

(Further description of the illustration on the front cover of this issue of Radio World.)

WHILE radio may be used for short distances, in place of telegraph lines, its real force lies, rather, in long-distance work, side by side with the cables. However, a most important development has taken place. It is the completion of a 1000-kilowatt supertube, the work of J. H. Payne, Jr. Mr. Payne created this tube in the research laboratories of the General Electric Company, Schenectady, New York, employing discoveries made by Dr. Irving Langmuir and Dr. A. W. Hull.

It is not intended or adapted for use on lighting circuits. Engineers had found that the major problem of tube development for radio has been solved insofar as the size tubes is concerned. They had demonstrated that almost any size tube could be made for radio work and operated successfully. But there was an undeveloped field for tubes in general engineering, especially where high-frequency generators or high-voltage rectifiers might be required.

Attention was directed to the development of superpower tubes for use in the generation and transmission of high voltage, direct current, and other engineering work.

The supertube has an output of 40 amperes at 250,000 volts—about 1000 kilowatts, or 1,000,000 watts. Dr. Langmuir, in describing the tube, says:

“This tube consists essentially of a water-cooled cylindrical anode thirty inches in diameter. In the axis of the anode is a tungsten filament four-tenths of an inch in diameter and twenty-two inches long. This filament is excited by a current of eighteen hundred amperes at ten thousand cycles, the filament excitation requiring about twenty kilowatts.

Another line of development is, therefore in progress: the production of tubes of high efficiency as well as tubes of larger output. The progress in this direction is more difficult and is apt to be slower than in the direction which, thus far, seemed more important. These

developments will come gradually, for the practical construction of powerful tubes giving thoroughly satisfactory operation requires considerable development. It would be boasting, however, to predict the limitation of the ultimate use of the vacuum tubes in the power field.

(C. Underwood & Underwood, N. Y.)

Close-up of the million-watt vacuum tube, fifty times more powerful than any now in use, which has been developed in the Research Laboratory of the General Electric Company by J. H. Payne, Jr.

How to Build a 100-Meter Concert Receiving Set

By Frederick J. Rumford, E. E., R. E.

Figure 1—Layout of panel with distance of holes to be drilled; also the position of the binding posts, knobs, contact points and rheostat. Suggested by Frederick J. Rumford. Drawn by S. Newman.

IN the near future many broadcasting stations in the United States will transmit on a wave length of 100 meters, more or less, because this range gives a radiophone station a larger band of wave lengths to operate over and will reduce interference from other stations. For instance, KDKA has broadcast concerts which have been received quite often by the writer at his home in Roxbury, Massachusetts.

I advise any radio fan who is interested to build himself one of these little receivers and have it hooked up so that the throwing of a switch will connect it with the antenna and ground circuits.

If your concert-receiver is unable to tune in 400 meters and over use this little set. It gives very good results on 100 meters.

Below are listed the necessary parts, and their respective cost, for the making of this set:

1 panel formica, or bakelite, 6" x 7" x 1/4"	\$1.26
1 base 6" x 6" x 1/2"	.25
1 vacuum-tube socket	.75
1 rheostat	1.25
1 jack	.75
1 plug	1.00
1 five-contact switch assembly complete	1.00
1 six-contact switch assembly complete	1.10
1 vacuum-tube bracket for socket	.25
8 binding posts	.80
1 set of screws, wire and accessories	.50
1/4 pound No. 22 D. C. C., magnet wire	.30
1 cardboard, or bakelite, tube, 3 1/2" diam., 2" depth	.35

Total \$9.56

First, all the marking of holes on the panel must be completed. The panel is now ready to mount the switch-assembly rheostat, the jack and the binding post. After this is done, we are ready to make the coil which will consist of a primary and tickler winding. The tube is first given several coats of shellac and left to dry. After drying, the primary winding is started about 1/4 of an inch from the end of the tube. There are 18 turns in this winding, with taps at the 9th, 11th and 13th turns. On the 18th, or final turn, there is a 1/2-inch space.

Next, wind the tickler coil, which

Figure 4—Wiring and connections of the taps of the primary and tickler coil. These make the set regenerative. Suggested by Frederick J. Rumford. Drawn by S. Newman.

Figure 2—Rear of the panel, indicating how the instruments should be mounted. Suggested by Frederick J. Rumford. Drawn by S. Newman.

has 20 turns of the same size of wire as used on the primary. This is tapped as follows: At the 11th, 13th, 15th, 17th and 20th. After the winding has been completed, the coil should be given two coats of insulating compound.

After the coils have dried, they should be mounted at the back of the panel by means of two machine screws with nuts, fastened firmly at the back, holding the coil-form firm and rigid. The taps are then connected to their respective posts.

The set is now ready to be wired. Careful attention should be paid to the wiring diagrams, figures 3 and 4. Regarding the two binding posts marked

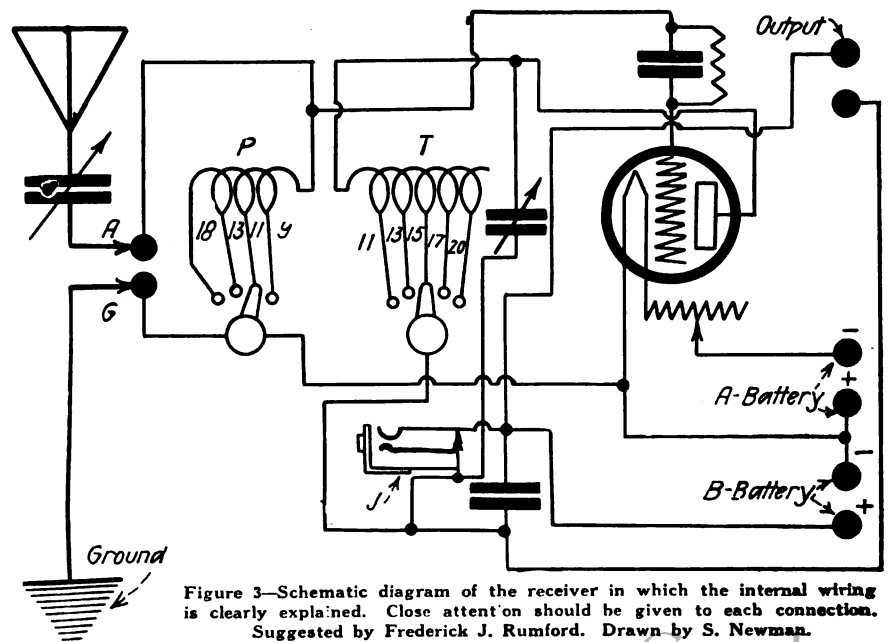

Figure 3—Schematic diagram of the receiver in which the internal wiring is clearly explained. Close attention should be given to each connection. Suggested by Frederick J. Rumford. Drawn by S. Newman.

United States May Be Divided Into Radio Zones

By Carl H. Butman

WASHINGTON, D. C.—The radio public is beginning to demand not only good entertainment and high-class transmission, but a greater range of reception. In other words, the listener-in wants to reach farther afield. His horizon is extending. He wants to hear the distant stations outside his city and state. The Department of Commerce radio officials, therefore, are making a survey of each radio district to see if there isn't some way by which this can be arranged.

One radio enthusiast says that, while he is appreciative of all his local stations, he sometimes wants "to go visiting by radio"—listen to some of the big stations outside the local field—just as he frequently likes to listen to the conversation of others than his immediate family whenever guests are present.

It's the same in radio broadcasting, he says.

In an effort to aid in seeking a solution of this new problem the Department of Commerce has written letters to its nine radio district-inspectors, stating that information reaching the department indicates that, throughout the country, a sentiment for silent local radio broadcasting periods is developing so that the listeners-in can hear the distant stations, which is often impossible when local stations are broadcasting. In some sections of the country steps for such an arrangement have already been taken. On the Pacific Coast, for example, what is known as the Pacific plan of time division has been amended so that, from 8 to 10 o'clock each evening, amateurs are silent, thus permitting the broadcasters to have a clear field.

At 10 o'clock the amateurs have a period, during which they may communicate without interruption. In other sections the local broadcasters remain silent for one evening a week, or for a few hours one or two evenings a week, so that those having sets capable of long-distance reception may pick up some of the powerful broadcasters outside their district. The department points out that there is a great fascination in listening to distant stations, and it is the opinion of the Radio Section that this wish of the radio public will meet with the cooperation of most of the broadcasting stations when it is understood. Broadcasters and local enthusiasts should advise local inspectors as to what they think of the plan or take it up with the department directly.

It may be found desirable to divide the United States into zones somewhat as it is divided into time zones, the stations in a particular zone having silent nights or periods of two hours each. It might be arranged so that

the broadcasters in the Eastern Time Zone would not transmit on Monday night; those in the Central Zone keeping quiet on Tuesday; Mountain Section, Wednesday, and the Pacific Coast on Thursday; all sending on the other nights. The department inspectors have been requested to bring this suggestion to the attention of owners of broadcasting stations in their districts and explain it to broadcasting and listening-in organizations. Reports from inspectors will indicate the desire on the part of the public and the attitude of the broadcasters, who must arrange the matter, as the department's plan is only a suggestion.

Radio fans who complain of interference must not forget, officials point out, that the execution of such a plan will not enable them to get long-distance stations unless they have good sets and know how to tune in properly. The scheme is expected to receive the endorsement of the public and broadcasters alike, but it can only be successfully carried out with the close cooperation of every one. The reports of inspectors are awaited in Washington with interest.

This Is Radio Station 8 BVZ Send Radio World a Photograph of Yours

Here is a set we would all like to own—look it over, amateurs, with a view to copying its especially neat and compact arrangement. The batteries are in a locker under the table and hidden from sight. The call letters of this station are 8 BVZ. Its owner is Nicholai H. Hiller, Jr., Carbondale, Pennsylvania. Mr. Hiller has a few other complete outfits spread out over the valley, but this is his outfit de luxe. If yours can match it, send a photograph to RADIO WORLD for publication.

(Continued from preceding page)

"Output," which really connect with the points of the jack: The reason for one of these sets should desire to hook-up an amplifier with this unit, it can be easily made by connecting jumper wires from these posts to the posts provided from them on the amplifier unit.

The variable condensers used in this set are of a small value in capacity, and the grid condenser is, also, of a very small capacity. The grid leak is one-half megohm.

The vacuum tube used is a radiotron U-V 200. The B battery is of 22 volts and the storage battery, 6 volts, 60 ampere hour.

Wide Field for Experimenting With Aerials

Construction of Antenna Involves Many Details Which, if Properly Attended to, Will Increase Efficiency of Receiving Set

By Donald Van Wyck

FOR the radioist interested in experimenting, there is an interesting field that may be easily tapped—experimenting with aerials of various types. Although RADIO WORLD has made clear the working of aerials, I will endeavor to cover another phase of the subject. Radio enthusiasts who live in apartment houses, in many cases, find it inconvenient to stretch an outdoor aerial. Where circumstances prevent this, there are only a few schemes whereby broadcast programs may be picked up. A loop antenna, an indoor aerial, or an aerial plug which fits into the electric-light socket, and permits the use of the lighting socket as a means of absorbing the radio impulses, may be substituted for the outdoor wires; but in no case will the signal strength be as loud as with an outdoor antenna. One thing that the amateur must remember: crystal detectors will not function satisfactorily with the indoor loop, as they are not amplifying detectors—but sensitive mineral detectors which will pick up and rectify if the outdoor antenna is used. They will function all right, but the range of the broadcasting station must be five or ten miles. For distance with the indoor loop aerial, vacuum tubes must be used with two stages of amplification, for good results.

A convenient way of installing a simple indoor antenna is to extend a length of No. 20 single cotton-covered copper wire around the room or down the hallway. If it is run along the moulding, any effect which may detract from the appearance of the room may be prevented. We must look for the *ground*. This can be had by connecting the *ground* connection from the receiving set to the cold-water pipes or to the radiator. This wire can be run along the baseboard, or a crack in the floor, making the wire unnoticeable. When making the connections to the cold-water pipes, or radiator, make sure to file, or clean, the spots where you intend to make the connection. This will give you a good electrical connection when finished.

Loop aerial used in conjunction with radio-frequency or superregenerative receiving sets. Good results have been accomplished with such an aerial. It has well-marked directional properties. It also has the advantage of eliminating interference. The loop aerial is used exclusively throughout the United States Naval Radio Compass stations for locating positions of ships.

The loop antenna requires a sensitive set of instruments such as a radio-frequency or a super-regenerative set for its successful operation; as the loop aerial is a poor absorber of radio energy, due to the fact that closed circuits have a tendency to hold energy instead of absorbing or radiating the signal. The loop aerial gives the greatest volume of signals when pointed toward the source of the incoming wave, and thus has a directional effect. Of course, the small-sized loop is what makes the signals weak; but there is a great chance to try some experimenting with one.

There are various ways of connecting the aerial, or loop, to the set, depending on the type of set used. However, the general method is to connect one end of the loop to the antenna terminal of the set and the other to the binding post of the set marked "Ground." When the loop aerial is employed, no actual ground connection is necessary.

The construction of a loop is shown clearly in the accompanying sketch. The simplicity is at once apparent. Two light pieces of wood

are made up in the form of an X about 4 or 5 feet in height. Across the ends of these pieces, smaller pieces are screwed. These pieces need not be over 6 inches long and should be notched to take the wires and hold them in place. The number of wires needed must be determined by experiment; but, as a starter, try about 8 or 10 turns. For the wire, almost anything will do. No. 18 ordinary bell wire will do. If the builder wishes, he may use No. 22 or No. 24 cotton-covered wire. The fact that the wire is insulated will not make the slightest difference. Simply start the wire wherever convenient and wind the form full, keeping the wires spaced evenly.

The completed loop may be mounted in such a way that it revolves easily, so that the radio operator may get the loudest signals and, at the same time, cut out a large amount of interference.

Another method of eliminating the outdoor antenna is the use of the condenser plug which enables the radio fan to use the house-lighting wires as the antenna without the trouble of installation. In some apartments, the plugs work very well; but success depends upon local conditions, particularly the manner in which the wires are strung. If the wires are shielded by metal ceilings or conduits, signals will not be as loud as if the wiring is open. If the building is surrounded by steel structures, the results will not be so pleasing.

Experiments seem to indicate that the plugs work best on the second and third floors, especially in frame or brick buildings. A regenerative set with two stages of amplification works well with the plug and will pick up broadcasting easily.

The antenna plug is a condenser, or a number of condensers, encased, which serve to prevent the live-wire line from surging through the set. The function of the plug is to afford a coupling similar to a condenser in a circuit, allowing the high-frequency radio currents picked up by the house wiring to flow through the receiver.

National Radio Week Executive Committee Ready for Action

Subsidiary Working Committees Will Be Appointed This Week

MAJOR J. Andrew White, chairman of the Executive Committee in charge of preparations for National Radio Week, to be observed from December 23 to 30 (inclusive) has appointed the following to complete the personnel of five members suggested at the meeting reported in *RADIO WORLD*, No. 32, dated November 4:

H. Gernsback, Kendall Banning, Lawrence A. Nixon, Arthur H. Haloran, and Roland Burke Hennessey. Arthur H. Lynch is treasurer.

This committee, with Major White as chairman, held a very important meeting on November 3 at Major White's offices, 326 Broadway, New York City, full details of which will be published next week.

Committees to take charge of the music and broadcasting programs, the publicity, the special meetings of dealers and manufacturers will be formed.

Enthusiasm prevails everywhere and National Radio Week promises to be the one big event of the year. *RADIO WORLD* has received many messages of praise, not only for suggesting the idea, but for passing it on to the radio field at large in order that all may take an equal interest.

Among the newspaper comment is the following from "The Globe," New York. It shows the spirit of one of the big, progressive newspapers of the Metropolis:

A brilliant idea has been conceived by R. B. Hennessey, editor of the *RADIO WORLD*, a weekly radio publication. Mr. Hennessey makes the suggestion that a National Radio Week be held from December 23 to 30, inclusive, during which time short talks appertaining to the season are to be personally delivered by high government officials and broadcasted from all broadcasting stations. The idea is an excellent one both from the viewpoint of the country itself and from that of the radio industry.

It is Mr. Hennessey's intention to weld the country together for one whole week through the agency of radio. Political talks, speeches on art and literature, entertainment in lighter vein for those who care not for the heavier subjects, and religious and scientific addresses by leaders in their respective fields.

The dates selected come at the season of Christmas, an opportune time for a venture of this nature. The wholesome advantages of life in this country and

MAJOR J. ANDREW WHITE
Chairman of the Executive Committee of
National Radio Week.

particularly at this time could not be brought to the attention of the nation in a better way than through the chain of broadcasting radio stations now available.

Of course, there is another thought

Radio Development in Cuba

Amateurs Enthusiastic Over Establishment of New High-Power Broadcasting Station in Havana

OWING to the lack of adequate broadcasting facilities, radio development in Cuba has not kept pace with the progress of radio transmission in the United States, says Assistant Trade Commissioner Livengood, Havana, in a report to the Department of Commerce but recently a high-power sending center has been established in the capital and the market for small receiving sets is expected to widen rapidly. This station has not yet made arrangements to supply broadcasting service, but it will do so soon. The apparatus of the company operating this station, which has a capacity of 500 watts, is an exact duplicate of that used by the New York Telephone and Telegraph Company in its Walker Street station. Test messages from the new Havana station have been heard as far away as Princeton, New Jersey. As in all tropical countries, Cuban enthu-

siasm have met with difficulty because of "static" disturbances. In spite of all obstacles, however, a considerable number of Cuban amateurs have been experimenting in receiving and transmission. In order to receive from United States stations, apparatus of the more expensive kind is necessary. With such sets, messages have been received from Memphis, Detroit, Pittsburgh, Jacksonville, Wichita, Kansas City, and Schenectady. Messages from Atlanta have been most successfully received in Havana.

Havana dealers are well equipped to supply radio apparatus in anticipation of broadcasting from the new Havana station. Interest in radio matters is thoroughly active, and when United States facilities are available, merchants believe that Cuba will offer a promising market.

United States Senate,
Washington, D. C.

Editor *RADIO WORLD*:—

I have had the pleasure on several occasions during the present campaign of speaking over the radio, and I fully appreciate its practical value in very many directions. The whole world is coming to appreciate its unlimited possibilities.

I heartily endorse your plan for the celebration of a National Radio Week, and shall be glad to do anything possible to make that celebration a success.

Very truly yours,
WILLIAM M. CALDER.

National Radio Week is to be an important event. The executive committee is seeking suggestions to make it a huge success. All radio fans and amateurs are invited to cooperate.

To many anxious inquirers: *RADIO WORLD* has no free list. One copy is sent as a voucher to each advertiser or advertising agent represented in current issues. All other copies are paid for on subscription or through the news trade.

Be a Booster for National Radio Week!

Single-Tube Superregenerative Receiver

By C. White, Associate A. I. E. E.

THE interest taken by amateurs in the development of the superregenerative circuit indicates that there is a preference for the more scientific receiver, although its actual construction does entail many difficulties in wiring. Up to the present time, many designs of this famous circuit have employed either two or three tubes, but the objection to such sets has mainly arisen from the necessary complexities of the general connections. Some radio fans tried to build a multi-tube superregenerator, but failed because they attempted to crowd the apparatus into too small a space. This is a common fault with most amateur construction, and the poor results are commonly indicated by all sorts of howling, audio-oscillations, and extremely sensitive tuning-adjustment without the desired amount of selectivity. Frequently, such troubles are caused by improper shielding or a lack of shielding of the component parts or groups of parts; or, perhaps, poor condensers and loose connections. So, no matter what type of modern circuit the novice is considering, it is paramount that he pay very careful attention to minor details of construction, which often determine the actual efficiency of the outfit.

The demand for a circuit employing the superregenerative principle with a single tube has been apparent from the start. This demand has been due to two chief facts; first, the two- and three-tube outfits have been very bulky and by no means easy to carry around, especially since a storage battery of very large capacity is needed to supply the filament currents. Second, although the results obtained have been truly remarkable, the cost, both initial and maintenance, has been far in excess of that which the average amateur is so disposed to pay. Hence many

have been at work trying to perfect a single-tube outfit that possesses most of the points of advantage of the larger types and still retains the outward and inward simplicity in design, and, also, is immune from excessive costs. Since it is rather hard to definitely connect scientific perfection and financial economy, we frequently must compromise between the two and make some slight sacrifices in favor of one or the other. The single-tube superregenerative receiver does not have the flexibility of control and the extremely fine selectivity, although in size and cost it is really in the class with the average regenerative-set employing variometers and a double-tuning circuit. It is quite simple and it is possible to make up a receiver that is very

good for traveling and demonstrating purposes by employing a WD-11 tube which requires only a 22½-volt B battery and an ordinary No. 6 type dry-cell to light the filament. Personally, I have seen a lecturer's radio set made on this principle which measured only one foot in each dimension. Except for a loop aerial and a loud speaker this receiver was very complete and ready to work in a moment's notice.

In Figure 1 is shown the general wiring connections. A vario-coupler with the stator as primary and the rotor as tickler coil was used. But if the amateur so desires, he may change the general tuning-circuit by using a vario-coupler with two rotors; the stator for the primary of the antennae-ground circuit, one rotor for the secondary, and the other for the regenerative tickler coil. While a double-circuit arrangement adds a certain amount of scientific refinement, I do not think it is advisable to incorporate such an expensive item as a double rotor vario-coupler in a single-tube set, especially since, with a loop aerial, it is quite easy to obtain good selectivity and a minimum of interference.

As illustrated, a 43-plate variable condenser is placed across the terminals of the stator and thus provides a method of sharp tuning. The regenerative coils consist of two honeycomb

Figure 2—Schematic design of a plate potential battery for a single-tube superregenerative receiver. Drawn by C. White.

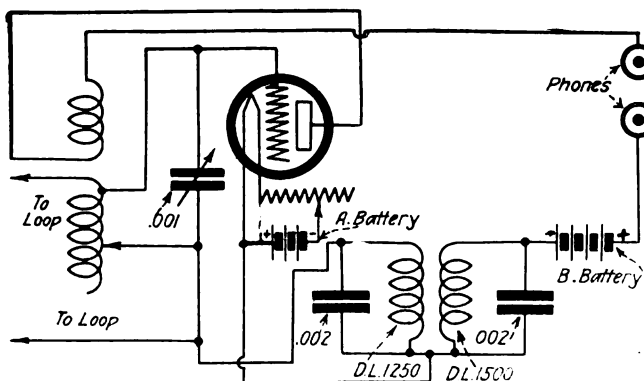

Figure 1—General wiring connections of the single-tube superregenerative set. If the amateur wishes he may change the general tuning-circuit by using a vario-coupler with two rotors; the stator for the primary of the antennae-ground circuit, one rotor for the secondary, and the other for the regenerative tickler coil. Suggested by C. White. Drawn by S. Newman.

Why it Is Necessary to "Tune In"

By Arthur G. Shirt

WHAT are you doing when you juggle with the slider on your tuning coil, or twirl the dials on your variable inductance?

"Why," you answer, "I'm tuning in." But there you stop. Why it is necessary to "tune in" perhaps never occurred to you. Therefore, an explanation couched in language everyone may understand, may not be amiss.

To begin with—the aerial. If no other explanation will quite cover the idea, the aerial is erected outside or inside, as the case may be, for the purpose of catching messages, music, speeches, and press reports, just as a rain barrel is given its place to catch rain water. Falling rain represents some energy, even if it is not generally utilized, and so does the entertainment which comes down through your aerial to your receiving set. It is of an entirely different kind, however, and peculiar to itself.

The sort of energy that we hope to capture when we string our antennae is what is known as "wave energy," so called because we can more readily conceive of it when it is compared to ocean waves. Every transmitting set in the

country sends out wave energy; but to avoid interference of the worst kind, the radioists send out waves of *different lengths*. Waves have length—and they are not spoken of as being so many feet long, or so many yards, but so many *meters*. Thus amateurs send on a wave length of 200 meters and less, broadcasting stations from 285 to 485, and government stations on 800 meters.

Whatever type of aerial you may put up, it will possess a neat little wave length all its own. It may be from 75 to over 200 meters, and may be determined beforehand by working out a well-known formula. If you had just a detector and a pair of phones attached to the end of your aerial, you would be limited to the reception of only those wave lengths which were the same as the natural wave-length of the aerial. Poor chance of ever getting anything with an arrangement like that. It is

"Radio will make this a bigger, better world."—Hoover.

apparent that you must have some means of raising or lowering the wave length of the aerial so that your receiver will respond to a wide range of stations.

This is done by means of a tuner. The tuner, as most of us know, is a coil of wire connected to the aerial and the ground, and forming the primary circuit of a receiving hook-up. All tuners—with the exception of block coils, such as honeycomb and spider—have some means whereby the number of turns of wire which are included in the circuit may be controlled. Either a slider or a dial will accomplish this; and by manipulating these devices you put your set in resonance—to use a word which means exactly the same as tuning—with as many different wave-lengths as the size of your coil will allow.

Hereafter, when you set out to tell anyone who is not familiar with radio why you are tuning in, say: "To place my set in resonance with the set which is sending out the music I want to get." Then they will understand, and, at the same time, give you credit for knowing what you are doing and why.

(Continued from preceding page)
coils, D-L 1250 and a D-L 1500, mounted so that they can be turned axially with respect to each other, thus varying the mutual coupling in order to definitely control the amplitude of the locally generated oscillations. It is highly recommended that a good make of mica condensers be used with these coils. If it is not possible to obtain .002 microfarads capacity in a single condenser, then such a capacity can be made up of two .001 microfarad condensers connected in parallel.

Although, as I have previously said, it is quite possible to make such an outfit extremely compact and portable by using a dry-cell type of vacuum tube with a low B-battery potential, still if the receiver is not to be moved about often, I would advise that a hard tube with a high-plate voltage be employed instead of the soft tube. With this set, a UV-202 tube with 200 volts, or thereabouts, on the plate will give far better volume and results in general than a UV-200 or UV-201. Naturally the average amateur will object to this on the ground that it is next to impossible to get a cheap reliable source of high potential that will stand the current drain of a power tube; but such is far from the actual fact. Small storage-cells for plate potential batteries can not only be purchased at an extremely reasonable price, but can be

made up by the amateur from \$10 to \$15 for a 150-cell battery (that is about 300 volts).

The general method is to obtain as many 1-inch by 7-inch test-tubes as there are cells, then cut from a 1/16th-inch lead sheet, strips about 1/2 inch by 18 inches in length for the plates. For the separators, a small stick of white wood may be placed between the two plates in each cell. Any type of device that will hold the cells rigidly in place, will suffice as a container for the whole battery; but as illustrated in Figure 2, it can be made up of ordinary wooden beams, bored just deep enough to make a firm resting place for the butt of the tube. This type of wooden base, or container, should be painted with at least two coats of black asphaltum paint in order to allay the eating action of the acid electrolyte. It is cheaper and safer to buy from some battery-service station, the electrolyte (dilute sulphuric acid) already mixed, then to endeavor to dilute concentrated sulphuric acid, which operation, if not properly done, will result in serious bodily harm to the mixer.

The potential of the terminal of the battery is determined by the initial potential of the first charge. Such a battery may first be charged and then recharged by either dividing the same into groups of three cells and connecting such groups in parallel with a 6-

volt D-C supply; or by dividing into groups of 55 cells, if a 110-volt D-C supply is available; or 110 cells for a 220-volt D-C system. The majority of amateurs will resort to the first method, using the same apparatus that they use to charge the 6-volt A battery. After charging has been accomplished, all the cells may then be connected in series for the regular B battery work.

I strongly recommend this type of receiver with a hard tube employing a high-plate potential. Under such conditions of operation, it is perfectly possible to receive from local stations using a loud speaker with a single vacuum-tube. For those who want the greatest possible results for the minimum amount of money invested, there is, possibly, no better style of vacuum-tube outfit to rival the superregenerative receiver employing one bulb. But the amateur who wishes an ultrafine receiver of the supertype, would do well to use a two- or three-tube outfit. The single-tube set is not as good, scientifically, as the multiple-tube regenerative. This is quite evident since we must sacrifice quite a bit of flexibility of control when we endeavor to make one tube play a dual role. Again I must say to anyone attempting to build any high-grade receiving apparatus that shielding must be perfectly accomplished if satisfactory results in sharp tuning are desired.

The Radio Primer

For Thousands of Beginners Who Are Coming into Radio Circles

Weekly A B C of Radio Facts and Principles Fully and Tersely Explained

By Lynn Brooks

What is a vacuum tube?

THE vacuum tube is a glass bulb shaped very much like the bulb of an incandescent lamp and of similar size. It contains three elements: grid, filament, and plate. It is called a vacuum tube because the air within it has been reduced to the lowest possible percentage.

In most of the present-day radio receivers, an instrument known as inductance, is employed to enable the fan, or novice, to operate his receiver on the different wave lengths. 2 is the variometer with its primary and secondary windings. 3 is the variometer used so much for the regenerative effect for amplification. 4 the honeycomb coil explained on this page. These instruments are important as they are mostly dealt with by the radioman.

What is the plate?

The plate may be either a wire mesh, a flat plate of nickel, or, as in some tubes, it may take a cylindrical form completely enclosing the other two elements.

What is the grid?

The grid is usually made of some fine wire mesh. It is a network of fine wire of tungsten, tantalum, or nickel, or a perforated plate of one of the same metals. One end of the grid is connected to the tuning coil and the other end is left free.

What is the filament?

The filament usually is made of finely drawn tungsten wire coiled in a spiral similar to the filament in the ordinary house-light. The filament is heated to incandescence by a 6-volt storage battery. The battery must not be over 6 volts.

What is a honeycomb coil?

In order to obtain the required

amount of wire for long wave-lengths it was found necessary to have large, or long, coils of bulky construction. Although at first thought it would seem preferable to wind the coils in more than one layer, radio engineers know that if this were done the final result would not be what it should be due to what is known as distributed capacity.

What is distributed capacity?

When the wires form a miniature condenser and these condensers are in their right places, they do not belong in a tuning coil—particularly when they are widely spread. So they are called “distributed capacity.” If the capacity were concentrated, the objection would no longer hold; but this is not so.

From what does the coil derive its name?

From the peculiar appearance of the finished coil. In winding inductances, none of the wires are ever parallel. They cross each other and always at right angles.

1 is a simple sketch showing the wiring diagram in connecting up a storage battery to the house current, when 110 volts direct current is available.

What is a variometer?

An instrument which serves to vary the inductance and the wave-length value of any circuit in which it may be used. It consists of a set of fixed windings and a set of movable windings, the latter being rotated on twin axes in the usual construction. When both sets of coils carry the current, or flow in the same direction, the variometer has the maximum inductance

Radio Hints

Useful Facts for the Beginner Who Wants to Know

FILAMENT rheostats are designed with a zero point which acts as a switch between the tube and the storage battery, but it sometimes happens that, in the hurry to close the station for the night, the rheostats are not turned off completely. This permits the storage battery in the circuit to discharge all night long through the resistance. To prevent this many fans have installed a separate switch, which, through practice, they accustom themselves to turn off before the rheostat is turned back to zero.

The increase in the use of the dry-cell tube is particularly noticeable. Up to a short time ago it was difficult to obtain these tubes, but the supply is now meeting the demand. For compact sets to be carried about in an automobile, or even in a pack on the back, dry-cell vacuum tubes are unusually well adapted.

All connections about a radio circuit must be soldered, but soldered correctly. There are some general hints that may be given, but judgment and experience are essential. The soldering copper must be clean and the tip well coated with solder. If the tip of the soldering copper is not bright it should be filed clean. It is then heated, care being taken that the tip is not in the soldering flux or paste, and the copper tip coated with solder. The wires are cleaned where the soldering is to be done, using fine sandpaper, then a small amount of soldering flux or paste is applied at the joint and the wires to be soldered are tinned or coated with solder before the wires are joined.

After the wires are tinned they are soldered together, using just enough solder to make the joint solid. The joint should not be jarred while the solder is still soft; to do so weakens the joint and gives the solder a dull appearance. A good soldered joint will be smooth and bright. All excess soldering flux or paste should be cleaned off. Gasoline or alcohol will assist in cleaning off the paste. This last point is sometimes overlooked, and the excess flux often causes the copper wires to corrode.

value or wave length. When coils are turned around so that the current flow in both sets is in opposite directions, the coils are said to be “bucking” one another. Then the inductance and wave length value are at a minimum.

De Forest Competitor Will Make "Movies" Talk

Device Invented by C. A. Hoxie, of the General Electric Company, Will Also Increase Scope of Broadcasting Entertainments

By B. S. Beach

AN ingenious apparatus for recording sounds on a photographic film to such an extent that the sound may afterward be reproduced in ordinary telephones or loud-speakers has been developed in the general engineering laboratory of the General Electric Company, and brings immeasurably nearer the day of the practical talking-movie.

It also means a boon to radio broadcasting studios. From a central studio—say, in New York City—the world's greatest artists may sing or speak before this machine which produces the film. Copies of this film may then be made and sent to other stations and reproduced with clearness.

It is claimed that it makes possible the talking-movie, for on a film of normal width can be the picture of the voice of the actor as well as the photographic record of his action, both voice and action absolutely synchronized because they are part of the same film.

C. A. Hoxie is credited with the invention of the device. It is called the Pallo-Photo-Phone. The record is made by causing the sound waves to produce vibrations on an exceedingly minute and very delicate mirror. A beam of light reflected by this mirror strikes a photographic film, which is kept in continuous motion. The film, when developed, shows a band of white with delicate markings on the edges, which correspond to the sound which has been reproduced. On account of the exceedingly small size of the mirror and its low inertia it is possible, by this means, to produce a sound record which includes the very delicate "overtones" which give quality to speech and musical sounds. This has not been so successfully accomplished by any other method of recording sound waves.

The reproduction of the sound from the film is accomplished by moving the film in front of an exceedingly delicate electrical device, which produces an electromotive force which varies with the amount of light which falls upon it. In the past attempts have been made to produce these results by means of selenium cells; but a selenium cell, the inventor claims, though it responds to the changes in the amount of light which it receives, does not respond with sufficient promptness to

produce results. There is a sluggishness in the response which seriously interferes with the quality of sound produced.

By an ingenious combination of vacuum tubes there has been produced an apparatus which responds to variations in the light falling on it with a speed which is so high that it can only be compared with the speed of light itself, or with the speed of propagation of wireless waves in space. Therefore, when this film is moved continuously in front of such a device the device produces an electric current which corresponds accurately with the original sound wave. This electric current may be used to actuate a telephone, or loud-speaker. It was used recently to operate the radio transmitting station WGY of the General Electric Company. The voice of the WGY announcer, "KH," was recorded on a photographic film and sent out by WGY with such accuracy that it was impossible to distinguish it from his voice as ordinarily directly transmitted from the station.

Apparatus to be used to convert sound waves into vibrations and then recorded on a moving-picture film. When the film is developed it shows a band of white with delicate markings

Radiofacts to Remember—Signals

Signals which come in weaker than the critical point of the detector make no impression on the detector and, therefore, are lost entirely. No matter how many steps of audio-frequency amplification may be piled up after the detector, the signals which have failed to actuate the detector will not be heard. With radio-frequency amplification, there is, virtually, no critical point

and even the weakest signal is built up to the desired degree before it is passed on to the detector, there to be rectified to audio-frequency currents which, if desired, may be passed on through one or more stages of audio-frequency amplification in order to build up the signal strength. This is done when great amplification is needed by the operator.

Odd Ways of Identifying Stations

By *Washington R. Service*

BROADCASTING stations are coming to be known by the voices of their announcers, their slogans, and the stunts they perform in order to identify their stations, as well as by the cryptic call letters assigned by the Department of Commerce.

There is little romance or euphony in the letters WSB, but listeners-in are very familiar with the big gong which rings "Bong! Bong! Bong!" to announce the Atlanta "Journal." The unmistakable southern accent of the broadcaster announcing the "Voice of the South" is also an indication that WSB is sending.

As the radio enthusiasts well know, there are a number of other stations using identifying phrases and sounds. For example, the "Courier-Journal" and "Times," WHAS, Louisville, Kentucky, plays a few bars of "My Old Kentucky Home." WDAJ, the Atlanta and West Point railroad station, at College Park, Georgia, has uniquely established its identity by

blowing four blasts of a locomotive whistle. When you hear this in your receivers you may be certain that WDAJ is broadcasting. The Naval Station at Anacostia, D. C., NOF, is known by the deep bass voice of the announcer.

It is not only in the Southland that these slogans and phrases have become popular. In the West, for instance, is the Palmer School of Chiropractic, Davenport, Iowa. "This is WOC," the announcer states; "out where the West begins." Another station identifies itself with: "Out where the corn grows tall." The voice of the spokesman at WOH, the Hatfield Electric Company, Indianapolis, might confuse one at first. He has a southern accent similar to that of WSB in Atlanta. The pronunciation of the simple word "and" like "a-yand" would hardly seem to locate a station, but ask any one who has heard "Mister," KDKA, Pittsburgh. They will admit that the drawled "a-yand" is a most positive identification.

The voices of the evening storytellers are well known by the small radioites. Some of the broadcasters sound a signal on the telegraph key, giving their call or some single letter indicative of their station besides the customary announcing of the letters.

Methods of announcing the time also serve to establish who is at the transmitter. Those who hear the Louisville "Courier-Journal" say they like the method of telling the time, as the hour approaches, with a simple statement, "Ten o'clock," when the minute hand reaches twelve, better than the standard tick-system of the Naval broadcasting stations.

When the Detroit "News" signs off the exact time is given. This is a benefit to those who have not set their timepieces for the night. Probably the custom will grow rapidly, and familiarity with the voices of broadcasters all over the country, as well as the mottoes and slogans of stations, will extend the acquaintance of listeners-in with the voices of the air.

Utilizing Ford Spark-Coils for Audio-Frequency Transformers

By *Ortherus Gordon*

Illustrations to guide the amateur in making transformers of Ford spark-coils.

WHEN the time comes to supplement your detector bulb with amplifiers, you will need in addition to the bulbs, sockets, filament rheostats, and two audio-frequency transformers. Any amateur who wishes to avoid paying the price of these transformers may make them himself provided he can get hold of two old Ford spark-coils. Most cities have automobile wrecking companies. Such concerns always have some of

these coils on hand at a very low price. With a little care and discretion, the amateur can pull the coil apart so that he has the primary, the secondary, and the make-and-break device in separate pieces. This done, throw the vibrator into your spare-parts locker and proceed to construct the transformer with what is left. Leave the primary and the core just as they are, but remove one section of the secondary. Ford-coil secondaries are made in two sections.

Place the remaining section in the center of the primary, bring the thin wires out free and block the ends with wooden partitions. Then you will have something similar to the design shown in the accompanying illustration.

Put two binding posts on one end and fasten the primary leads to them. The secondary leads may be taken and made fast to binding posts on the other end. A brass piece bent in staple shape, as shown, will serve to hold together the wooden ends and, at the same time, provide a means of screwing the finished transformer down to the table or baseboard. The whole makes a satisfactory audio-frequency transformer.

The Rheostat's Work

IN radio a rheostat connects the storage A-battery with the filaments of the vacuum tube. The rheostat is the valve which permits the operator to increase the electric current going from the storage A-battery to the filament. Rheostats are heat regulators. Heat drives off the electrons from the filament to the plate. When the tube shows a dull red glow the temperature is about 1800 degrees, and electrons are then beginning to be cast off. When the filament is white hot the temperature is 2050 degrees. As each degree of heat is increased from about 1800 degrees a tremendous increased proportion of electrons is cast off.

Elaborate Radio Equipment of the New Italian Liner "Julius Caesar"

(Both photographs C. Kadel & Herbert)

THE "Julius Caesar," the newest of fast ocean liners flying the flag of Italy, has one of the most modern radio sets on any passenger ship. Her transmitting and receiving equipment makes it possible for her to keep in communication with either continent when crossing the Atlantic. The photograph at the top shows the interior of the radio room. The numerals designate the various pieces of apparatus as follows: 1—The receiving gear. 2—Charging panel to keep the batteries charged in accordance with the laws of radio. 3—The main switchboard with its layout of meters. 4—The starting box by which the main motor-generator is set in motion to operate the main transmitting set. 5—The noise-proof cabin where the motor-generator is placed. 6—The main telegraph-key to operate the transmitter. 7—Continuous-wave (C-W) transmitter. 8—The wall; sometimes called the "deck insulators." 9—The wave changer which makes it possible to work on various wave-lengths. These cover all the important parts of the station. The illustration at the left shows Joseph Garosi, first radio operator, sending a radiogram in mid-ocean.

It is of utmost importance to employ all this equipment. When it becomes necessary to work long-distance (DX work) in order to clear the ship's daily traffic of messages, the continuous wave (C-W) transmitter is "cut in" the circuit and used. Not only does this transmitter enable the operator to cover a long range, but, at the same time—due to the wave being continuous—eliminates much of the interference that is found in undamped transmitters. Another feature of the C-W transmitter is this: It functions best when employing the higher wave-lengths. Usually 600 meters are used, but there are times when the transmitter is shifted to operate on a 2400-meter wave-length.

Radiograms

Latest Important News of Radio Garnered from the World Over, and Reduced to Short Wave-Lengths for the Busy Reader.

RADIO was utilized successfully by a ship's surgeon on the high seas to secure advice for a passenger suffering from heart trouble. Henry W. Kibbe, an official of the Cadillac Motor Company, recently went to Argentine on the Lamport & Holt liner, "Van Dyck," for his health. He was suddenly stricken with rheumatism of the heart. On the return trip he was under the constant attention of two nurses and the ship's surgeon, Dr. A. R. Jenkins, who daily used the ship's radio in consultation with the best heart specialists in the United States in order to safeguard Kibbe's life. The patient was taken to Flower Hospital after the "Van Dyck" docked in New York City.

* * *

So many requests for assistance in solving radio problems have reached the Central Technical School, Toronto, Canada, that a special night-class has been started for instruction in building, operation and general care of radio receiving sets. There is a complete receiving-set in one of the electrical rooms and considerable research work is being done. Two hundred students have a good all-round knowledge of practical radio and are able to construct parts, in addition to efficiently handling receiving apparatus.

* * *

Legislation is about to be enacted in Chili, putting radio on a basis similar to its control in the United States, with broadcasting stations maintained by private enterprise.

* * *

A committee of radio experts in France, which have been conducting research with telegraphy on moving trains on the Paris-Orleans line, reports that its efforts have met with success. A small portable apparatus was used, and long-distance signals were clearly received while the train was moving at high speed. During their experiments members of the committee set up apparatus at some of the stations on the tour and invited farmers and others to listen-in.

* * *

The American Radio Relay League operating department will conduct the third series of transatlantic tests with the co-operation of the English, French and Dutch amateurs in December this year. While no definite dates for the final tests have been decided upon, pending suggestions from England, France and Holland, the probable dates are December 12 to 31, inclusive. During the first ten days of the tests American and Canadian amateurs will transmit signals for reception in England, France and Holland. The best American transmitters, as determined by reception reports from the European amateurs, will be selected to broadcast the result of the reception of signals transmitted by English and French amateurs during the last ten days of the tests, the same as MUU and WII did last year. Transmitting will be from 7 p. m. of one day to 1 a. m., the following day, during the first ten days; "listening-in" will be from 8 p. m. of one day to 2 a. m., the following day, in the second ten-day period.

Two Wizards of Electricity Meet

(C. International News Reel)

Thomas A. Edison and Dr. Charles P. Steinmetz, chief consulting engineer of the General Electric Company. Dr. Steinmetz is showing Mr. Edison a piece of wood which, but a few moments before, he had gouged from a limb of a tree with his new artificial lightning-making machine.

Weather forecasts sent out by the National Meteorological Office, France, for the benefit of agriculturists, are received on radio sets installed at parish schools or gendarmerie stations, at a cost of 200 francs. Weather warnings are given locally by sounding a bell.

* * *

A series of New England Radio Nights to take place during the fall and winter months, is the latest announcement in the broadcasting programme of the Amrad station. It is planned to devote specified meetings at periodic intervals to certain organizations who will be responsible for the programme during the time allotted.

* * *

Over two hundred Rochester, New York, radio fans have formed the Rochester Radio Telegraph Club, the object being to study the continental Morse code used in the transmission of radio signals. Headquarters have been established at 36 South Avenue. David Ryan, former navy radio instructor, stationed at Pelham Bay, New York, during the World War, will be the instructor.

* * *

The United States is now divided into eight radio districts with a radio inspector under the Department of Commerce in charge of each district. Radio inspectors have offices in Boston, New York, Baltimore, Savannah, New Orleans, Detroit, Chicago and San Francisco. The Department of Commerce has licensed about 20,300 stations, and of this number 3,575 are ship and commercial land stations, 11 trans-ocean, 560 special land stations such as colleges and experimental stations, 565 broadcasting stations and 15,780 amateur stations.

* * *

Montclair, New Jersey, has installed in its high school an aerial equal in size to some of the broadcasting stations. The receiving set is in the physics department and many of the pupils are licensed operators.

* * *

A radio station at Madras, India, will probably be converted into highspeed automatic plant for operation inland and also to Rangoon.

* * *

Over 18,000 ex-service men and women are receiving instruction in radio in the Knights of Columbus schools, New Haven, Connecticut, in special radio classes organized by the K. of C., and through the Knights' correspondence school. The latest figures compiled show that those taking courses in auto-mechanics under the same auspices approximate 35,000; but the proportionate increase in the popularity of the study gives radio a large increase over figures of 1921.

* * *

T. R. McElroy, of Boston, who won the receiving contest in Boston recently, broke his own record with a speed of fifty-eight words per minute, with five errors.

* * *

Portugal has awakened to radio! Consul General Hollis, Lisbon, reports to the Department of Commerce that by a recent bill the Portuguese government is authorized to contract with the Marconi Wireless Telegraph Co., Ltd., for a system of radiotelegraph and radiotelephone stations in Lisbon, the Azores, Madeira, Cape Verde, Angola and Mozambique. The bill provides that this authority must be exercised within three months from the date of approval so that all installations may be complete within four years. The Marconi Company must bind itself to organize a Portuguese radiotelegraph and telephone company, the board of directors of which shall be composed of seven members, five of whom shall be Portuguese citizens. At least two-thirds of the capital of the new company is to be reserved for subscription in Portugal. If this portion of the stock is not subscribed, the unsubscribed portion may be taken up by the government or by any other interest.

Over 2,000 hours of operating time, conservatively estimated to be worth \$150,000, has been saved to navigation interests in the Great Lakes in a single season by radio advice as to weather conditions.

* * *

All ships sailing from American harbors, and carrying fifty persons or over, are required by law to maintain and operate a radio set capable of covering at least 100 miles.

* * *

The broadcasting station of Spokane, Washington, has decided to suspend operations two nights a week so that owners of sets there may hear concerts from outside points.

Radio and the Woman

By
Crystal D. Tector

SINCE the last number of RADIO WORLD went to its readers, I have been besieged with telephone calls in regard to National Radio Week. It is too early for letters, but I expect that by the time I sit down to indite my next "copy" for this department, I will have heard from a great many of you—and I shall try to answer you all as cheerfully as I know you will write me. In fact, I have taken Friend Husband's advice, and engaged a secretary. She will open and sort my mail, and I shall dictate to her, as speedily as possible, answers to all letters that come to me, so there will be no delay. I will gladly help you to perfect any arrangements you have in mind to make The Week a huge success.

* * *

We—and when I use that much abused pronoun—I mean a partnership with all radioists who have the best interest of National Radio Week at heart; well, we want this very important event to extend as far as possible—even into every town in the United States. It does seem to me that it should be made a week of social functions—radio dances and dinners and parties—and even radio teas. I can imagine nothing more attractive than a beautiful reception room, flowers and greens everywhere, pretty girls as hostesses, and a receiving set hidden somewhere "exhaling" the most wonderful dance music with songs and recitations in between.

* * *

Teas are very much in vogue, here in the East. In fact, they have become one of the most popular forms of social pastime. The men seem to like them—and although they usually begin about four o'clock in the afternoon they frequently run far into the night. Recently a very charming friend of mine, who is noted for her social affairs, invited me to one of her teas. It was very gay, but she seemed to think that something new would have to be created in order to keep up the interest in such affairs.

* * *

I suggested to her that she give another tea and let me bring my radio set. Well, she knew as much about radio as a kitten, and when I asked her if there was an antenna on the roof, she replied that she didn't know because she "sent all her washing to a laundry!" However, that part of it has been overcome. She lives right in the heart of the most thickly populated

section of New York City and pays a rent that would stagger some of us. So, her landlord found no objection when the matter of erecting an aerial on his roof was finally explained to him. She became so anxious that she wanted to give the radio tea within two weeks. The most attractive cards had been prepared and were all ready to be mailed, when I prevailed on her to postpone her event until National Radio Week. She demurred—wanted to be first in the field and all that sort of thing; but when I told her how gay and festive and full of wonder that week would be, she gladly capitulated, and put it off.

* * *

She has asked me to be "hostess of honor." The event will take place on Tuesday afternoon, December 26. The invitations have been designed by a clever artist. The design is a pretty girl sitting before a receiving set and over the invisible ether comes a voice, represented by tiny waves, which is asking, "Will you come to my radio tea?" In one corner are the hostess' name and address, and the date. It is all attractive and neat, and very much in keeping with both radio and what the society reporters are pleased to call "A swell affair." Being a generous person, she has told me that I may go to any cost—and she will foot the bill—if I need anything to improve my set. "Get two sets, my dear, if you need them," was her *naïve* remark!

* * *

Friend Husband says that I will wear myself to a frazzle with all I have to do to make her affair a success. He always throws cold water on things I undertake—at first—but he always comes around when I succeed; and I generally do. And I am going to see that this affair does not slip up in any way.

* * *

I was mentioning the many telephone calls I have had regarding National Radio Week. I did not mind answering one of them—even if one—a man, at that—called one chilly night at one a. m., and—Friend Husband answered the call! He didn't say anything—just looked! My late 'phone caller wanted to know if I could suggest his name for a position as publicity disseminator. Don't blame the man. He is just a good example of the American spirit. He thought he saw a chance to make some money, and he wanted to be "Johnny on the spot." That man will succeed.

Boy Scouts Will Listen to Radio at Any Time

(C. International News Reel)

Remarkable photograph of a troop of Boy Scouts listening in while a broadcast story is coming over the ether. It is claimed that no other form of entertainment so deeply interests and holds the attention of boys.

(Above) The interior of the after cabin of the flying boat Miami, Florida; Cuba, and the West Indies. The photograph in a small space, but the completeness of it has rendered the "boat." Note the big loop aerial and the receiving set. To withstanding the noise made by the propellers of the flying boat is distinctly heard.

otos of a Busy Radio

(Right) When the Prince of Wales recently sent a radio message to the Boy Scouts of Great Britain, the event was regarded as something of unusual radio importance in his country. The prince has become a radio fan and has induced his royal father to install a set in St. James Palace. The photograph shows a company of Scouts listening to the message.

(C. Central News, Ltd., London)

(Left) Thomas A. Edison, on his first visit in twenty-five years to the General Electric Company's plant at Schenectady, New York, was introduced to some of the most recently developed tubes used in connection with radio broadcasting and reception. Mr. Edison is shown in the photograph with the new Langmuir 20-kilowatt vacuum tube which successfully hurled a radio message across the Atlantic, at the left is George F. Morrison, vice-president of the General Electric Company, in charge of the Edison lamp works at Harrison, New Jersey. In the center is Dr. Irving Langmuir, radio research engineer, of the General Electric Company, who invented the 20-kilowatt tube.

(C. Kadel & Herbert)

(Above) The first passenger in the world to be transferred to a submarine from an airplane was Secretary of the Navy Edwin L. Denby. The submarine was summoned to its position by a radio message from the airplane.

(Right) Alan Edwards, formerly a radio engineer, is now singing and acting his way to fame in "The Gingham Girl," one of New York's successful musical comedies. He is the proud possessor of one of the smallest radio sets in the world. It has a two-bulb regenerator honeycomb-coil, a detector, a two-stage amplifier, and can be tuned to 2,500 meters. It is built into a soap box which is covered with leather—the finished article closely resembling a camera. At a recent radio show in New York, this set won first prize. Between the acts of every performance, Mr. Edwards entertains the other members of the company with concert music and other broadcast numbers. By leaving the door of his dressing room open, the broadcast program wafts through the "back of the stage" area. Mr. Edwards, as one may surmise, built his prize set. He has also built similar sets for Richard E. Enright, Commissioner of Police, New York City; Miss Pearl White, the moving picture star; Miss Nora Bayes, singer of popular songs; and others. He is a young man of many talents and a staunch believer in radio.

Answers to Readers

I WISH to construct a two-tube super-regenerative set and am in doubt about the vario-coupler. Would an inductance do, and would it work better than a vario-coupler? The inductance to which I have reference, is wound on a tube 3 inches in diameter and about 8 inches long. The wiring is started in the center of the form and 80 turns are wound for the tuning inductances, tapped at 5, 10, 15, 20, 25, 30, 45, 50, 60, 80. Adjacent to the tuning inductance is wound the feed-back, tapped at 10, 20, 30 and every tenth turn until the 100th turn. I am using this coil satisfactorily in a regenerative set. I would like to use this coil because I cannot get a hundred turns on a rotor, as it isn't large enough. Would a smaller wire do?—Müller Hotchkin, Wichita Falls, Texas.

You will not get very satisfactory results with the tuning coil and feed-back wound on the same tube. With an arrangement of this sort, coupling cannot be secured perfectly. This is a very important function with the superregenerator. I would suggest that you rewind the secondary with a smaller wire, or you might try placing the variometer in series with the rotor coil having the variometer in an inductive relation to the vario-coupler. Its exact position as regards to the vario-coupler must be determined by experiment.

I have a crystal set, and would like to see a schematic diagram of the hook-up. I believe I have made a bad connection somewhere which makes it impossible for me to hear. Will you help me out?—Joe Thompson, Bar Harbor, Maine.

Schematic design requested by Mr. Joe Thompson, Bar Harbor, Maine.

The accompanying sketch shows the correct hook-up for a crystal set. When connecting your instruments, be sure to get the connections right.

I wish to construct a crystal receiving-set employing a double-slide tuning coil, and a variable condenser in the aerial lead-in with a fixed-phone condenser. It is desirable that the coil be as short as possible, but long enough to insure the reception of 400 meters. Assuming a properly installed aerial 100 feet long, with a 30-foot lead-in, what should be the diameter of the coil and how long the winding? Would a coil wound on a solid wooden block be as efficient as one wound on the regulation cardboard tube? If so, would a coil wound on a flat wooden block of equal circumference be equally as efficient?—Charles Manning, Toledo, Ohio.

Your coil should be about 3½ inches in diameter and wound for 3 inches of its length with No. 22 wire. A solid core is not as efficient when it is round and, therefore, a flat wooden block is much less efficient than a round one.

My set consists of a loose coupler, a crystal detector, a fixed condenser, a head set of 2,200 ohms, and a one-wire aerial about 100 feet long. The primary of my loose coupler is 8 by 4 inches, and has 253 turns of No. 22 enameled wire. The secondary is 6 by ¾ inches, and has 240 turns of No. 24 covered enameled wire, with 72 taps taken off every 20 turns. What broadcast stations should I get? How far can I receive? What is my approximate wavelength?—Nicholas Mikoff, Salt Lake City, Utah.

It is quite impossible to tell your range, and guarantee the stations you will hear. Sets of the type you have generally have a maximum range of 25 miles. You should hear the broadcasting stations near you within this radius. Your maximum wavelength is, approximately, 1,500 meters.

Can I use an Arkay horn with my galena set? I have one pair of phones—and my wife and two children must look on.—Herbert Harrison, Floral Park, N. Y.

Unless you hear the music a foot from the phones, it would be very little use to install a horn. It would be better to buy two more pairs of phones, hook them all up in series, and hand one to each member of the family.

I have a regenerative set and am using an aeriotron detector tube. What parts will I need to amplify it one step? Is it necessary to disconnect the B battery when the set is not in use?—Edgar Smith, Pasadena, Cal.

You will need an amplifying transformer, a tube socket, an amplifier tube, a rheostat—preferably a good rheostat—and a 45-volt variable B battery.

I am making a variometer at home, but I find that it is difficult to make a ball-shaped rotor without a turning lathe. Is a cylindrical rotor as satisfactory? I intend to use the variometer to tune the plate circuit to make my set regenerative.—Arthur Beal, Flatbush, N. Y.

In order to produce regeneration, the control of the tuning in the plate circuit should be unusually fine. This means that the two windings of the variometer should be as close together as you can make them. For this purpose, a ball-shaped rotor is far superior to a cylindrical rotor. In a variometer of the latter type, the two windings are eccentrically coupled and the control of the inductance less fine. Some amateurs improve their cylindrical rotors by building them up with strips of paper, gradually decreasing the width of the strip as it is wound on.

Who is NOM and where located?—Paul Reiser, New York City.

Probably you heard NOF, the Naval experiment station at Anacostia, D. C.

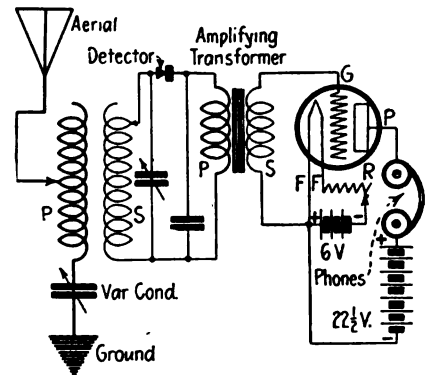

What are the advantages of a vernier rheostat?—Frank Malone, Pawtucket, R. I.

A vernier adjustment is absolutely imperative in a regenerative receiver in order to get what is known as the zero-beat adjustment for the reception of radio-telephony. This is the adjustment at the point where there is no self-heterodyning in your set, or between the set itself and the carrier of the transmitting station. It is the point where the music is purest and freest from distortion, and may be obtained only by a very minute adjustment.

Will a tin roof beneath my aerial have any effect on the signal? How will this effect long-distance receiving?—John Mohaupt, Omaha, Neb.

With a tin roof under your aerial some of the signal strength will be absorbed by the metal. It is more or less a means of bringing your ground up to the roof. By all means keep your aerial and lead-in free from all metal structures. It will be noticed that with a properly erected aerial, free from any metallic structures, and a short lead-in, there should be satisfactory reception. Do not try to hear distant stations all in the first week. Learn your set and the direction from which the loudest signals come and make changes accordingly. By all means be patient with your set. One wrong connection will make the whole set sound like a boiler shop.

I understand that an amplifier may be connected to a crystal-detector set. Is this possible? If so, will you publish a diagram showing how it is done?—Peter Lesser, Phoenix, Arizona.

Schematic design requested by Mr. Peter Lesser, Phoenix, Arizona.

Your understanding is correct. An amplifier may be used with a crystal detector. The accompanying diagram shows how. Be careful of the connections.

I intend to change my crystal set to a bulb set. Is the 2½-bulb as efficient as the usual type of detector? What kind of a B battery is required?—Paul Luke, Montclair, N. J.

You can change this set very easily, but the tube to which you refer is the 1½-volt type, the Aeriotron tube. This tube is just as good as the regular kind. The B battery should be about 22½ volts. Sometimes, however, slightly less is found to be an improvement.

How are the rotor and stator of a variometer connected? Is a regenerative set composed of a vario-coupler and two variometers? Why is it that I can only hear WJZ at the same place that I hear WVP?—Frank Ludwig, New London, Conn.

The rotor and stator are connected in series with each other. The two-variometer set is the most efficient. You will sometimes hear WVP, although on a 1,450 meter, on one of its harmonics, which is about 360 meters, is same as that of WJZ.

If U-V 201 tubes are used on the super-regenerative set, what adjustments are required?—Fred Nagel, Port Richmond, S. I.

If you use U-V 201 tubes in place of 202, it will be necessary for you to cut down on the amount of the plate voltage. In that event we suggest that 80 volts be used on the plate circuit of the first two tubes and 120 volts on the plate of the third tube. No other change is necessary.

Building Your Own Fixed Condenser

Figure 1—How the tinfoil should be placed. Dotted lines indicate the tinfoil. Even lines indicate the mica. Drawn by S. Newman.

Figure 2—Showing how the tinfoil rests upon the mica. Drawn by S. Newman.

FOR the best results with a receiving set, be sure to have a small fixed condenser connected across the head set. A fixed condenser of this type is very easy and simple to construct; but some care must be taken to smooth out the tin foil to avoid blisters and the sheets must be uniform. A condenser for this purpose may be made by most anyone. By securing the following material, you will have, approximately, the capacity of a .002 mfd., condenser. Purchase 7 sheets of tin foil, 1½ inches long by ¾ of an inch wide; 7 sheets of mica, 1 inch wide by 1¼ inches long; the

mica running about three-thousandths of an inch in thickness. Place a piece of mica on the table. Next take a piece of tin foil and lay it in such a manner that it laps over, as shown in Figure 1. Follow these operations until you have alternated the tin foil strips each time. Here you will notice that, when completed, there will be 3 tin foil taps on one side and 4 on the other. By bunching each of the tin foil laps on each side, they may be connected to a binding post and the other sides bunching to another binding post. They may be compressed and placed in a box ready for any receiver.

WHEN you buy a Magnavox, you are not just buying a horn connected to the ordinary telephone receiver. The electrodynamic principle involved in the construction of Magnavox Radio is recognized as the only satisfactory principle by which a reproducer may be constructed.

With the Magnavox, the incoming signal is electrically amplified—the horn or bell merely projects this amplified signal into the air.

R-2 Magnavox Radio with 18-inch horn

THIS instrument is intended for those who wish the utmost in amplifying power: for large audiences, dance halls, etc., but requires only .6 of an ampere for the field.

Price, \$85.00

R-3 Magnavox Radio with 14-inch horn

SAME in principle and construction throughout as Type R-2. Is ideal for use in homes, offices, amateur stations, etc.

Requires one ampere field current from your filament battery.

Price, \$45.00

Magnavox Power Amplifier—Model C

CAN be used with any "B" battery voltage which the power tube may require for best amplification.

Let "Radio World" Test Your Goods

MANY buyers of radio goods have been "STUNG." At some time they bought something that was not right or would not work.

Inexperienced manufacturers have rushed into the manufacture of radio goods in the past eight months while the public in its eagerness to buy has been willing to take almost anything. Buyers are now twice shy and cautious. They want to **KNOW** the goods are right before parting with their money.

Our seventy thousand radio buyers who read **RADIO WORLD** each week, have faith in it. They know that **RADIO WORLD** does no merchandising, has nothing to sell, that its opinions cannot be bought. Therefore, **RADIO WORLD'S** endorsement means something.

Manufacturers, send a sample of your goods to our Technical Editor, Fred Charles Ehlert, 9006 Pleasant Street, Queens, Long Island, N. Y. It will be carefully tested and returned. If your goods satisfy our experts, **RADIO WORLD'S** endorsement will be published in our merchandise department without charge or obligation of any kind on your part. When the radio purchaser sees a published test in **RADIO WORLD** with the seal accompanying this editorial attached, he will know that the product stands for perfection and has the guarantee of **RADIO WORLD**.

22 Exhibitors Already for American Radio Exposition

TWENTY-TWO representative manufacturers have already contracted for space in the American Radio Exposition to be held at Grand Central Palace, New York City, December 21 to 31 inclusive.

These firms are the following:

- Western Electric Company, Inc., New York City.
- Radio Corporation of America, New York City.
- C. Brandes, Inc., New York City.
- National Carbon Company, Long Island City, New York.
- Novo Battery Company, New York City.
- Sleeper Radio Company, New York City.
- General Insulate Company, Brooklyn, New York.
- Sound Wave Corporation, Brooklyn, New York.
- Pacent Electric Company, New York City.
- Stromberg - Carlson Manufacturing Company, Rochester, New York.
- Holtzer-Cabot Company, Boston.
- National Airphone Corporation, New York City.
- Clapp-Eastham Company, Cambridge, Massachusetts.
- Hutchison Radio Company, New York City.
- Henry Hyman & Company, New York City.
- DeForest Radio Tel. & Tel. Co., Jersey City, New Jersey.
- Dubilier Condenser Co., Inc., New York City.

In addition to the twenty-two contracts mentioned, nineteen more of the principal manufacturers have made reservations for space.

Heard at the Radio Counter

A Conversation Between Customer and Radio Clerk

(Part IV)

I AM seeking information regarding my aerial and would like to know if you can help out a good fan."

"Shoot! I'll tell you anything regarding aeri- als if within my power, Mr. Customer."

"Well, I own my house and have erected an inverted L about seventy-five feet long, directional north by east, fifteen feet high from the top of a fifteen-foot pole—which is at the front of the house—to another fifteen-foot pole erected on the house in the rear of mine. Now, when I use this aerial, I can only get the broadcasting station from a certain direction and, sometimes, find it hard to tune. Signals are also of a weak nature. The receiver is O. K."

"May I ask what your roof is made of?"

"The roof is of tin—on both houses."

"Well, I'll explain your trouble regarding weak signals. When your aerial is in operation, one may say that the earth, or ground, is your roof due to the fact that the tin roof is grounded. It acts, in this case, as a ground. Try and get your aerial so it lays in a position over the actual ground. Point your aerial towards the station you wish to hear. Take off the lead-in at the nearest end of this wire. Use about seventy-five feet and try out your set. I am sure this will aid you in every respect."

"Thank you for this advice and, by the way, give me three small electrose insulators."

"Right! Here they are—and success to the re- modelling of your antenna."

"Good-bye."

(To be continued)

Stable Firms Will Aid Radio

A SHORT time ago, one of the leading manufacturers of automotive equipment appeared on the radio horizon with a new line of well-designed and exceptionally well constructed apparatus. Every part of the equipment exhibited the thought and care

New Firms and Corporations

(The firms and corporations mentioned in these columns can be reached by communicating with the attorneys, whose addresses are given whenever possible.)

American Lamp-o-Phone Corp., Manhattan, make phonographs, \$50,000; H. H. Stevens, M. H. Elvidge, F. Riera. (Attorney, L. J. Feinstein, 47 West 34th St., New York.)

Ipcos Electrical Sales Co., Manhattan, electrical contracting, \$10,000; H. E. Kreindler, F. Padwe. (Attorney, L. Perkin, 261 Broadway, New York.)

Sta-Brite Electric Corp., Manhattan, \$10,000; same as preceding.

Associated Radio Manufacturing, New York, \$760,000. (U. S. Corporation Co.)

Capital Increases

The Bakelite Corporation, New York, has increased its capital stock from \$3,100,000 to \$5,100,000.

Radio Real Estate Corp. of America, Manhattan, \$2,000,000; S. B. Howard, G. V. Reilly, H. C. Hand. (Attorney, S. Ryan, Albany, N. Y.)

Jaworsky Electrical Co., Buffalo, supply business, \$25,000; L. A. Jaworsky, M. Polcyn, J. Mayer, Jr. (Attorney, A. B. Borkowat, Buffalo, N. Y.)

Change of Name

The Philadelphia Radiophone Company has changed its name to Durham & Co., Inc.

Coming Events

The editors of **RADIO WORLD** will gladly publish news items of all contemplated radio shows and expositions. Keep us posted by mailing full information.

SECOND NATIONAL RADIO EXPOSITION, direction International Trade Exposition Co., Chicago, January 13 to 20, inclusive, 1923, George A. King, director of publicity, 417 South Dearborn Street, Chicago, Ill.

PERMANENT RADIO FAIR FOR BUYERS, Hotel Imperial, New York City. Open from September, 1922, to May, 1923.

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, December 21 to 31. Colwell & Korbell, Fisk Building, New York City, directors of publicity.

INTERNATIONAL RADIO SHOW, Madison Square Garden, New York City, November 20 to 25, inclusive. E. C. Buchignani, director of publicity.

SOUTHEASTERN RADIO EXPOSITION, Auditorium Armory, Atlanta, Georgia, December 4 to 9, inclusive. Co-operative Radio Sales Assn., 295 Peachtree St.

SECOND DISTRICT RADIO CONVENTION, Hotel Pennsylvania, New York City, March 1, 2, and 3, 1923.

of an established manufacturer of precision mechanisms, says "The Globe," New York.

Within the last few days a second manufacturer whose name is synonymous with old-fashioned conservatism appeared in a small way as a maker of refined radio parts. This firm, like the first, had appreciated the business that awaited them in the radio industry, but unlike a large proportion of manufacturers that have sprung up over night, these old time concerns were satisfied to wait until they had perfected a line of goods that they knew were right.

Still a third company, long affiliated with things electrical, is reported to be deeply interested in the invention of a scientific worker in the east. This invention, if found to do all that its discoverer claims for it, will go far toward relieving the intense patent situation that has been the bogyman of radio manufacturers and dealers.

Share Your Radio Knowledge with Your Brother Fans Through Radio World

Every Amateur Likes to Know What the Other Fellow Is Doing

Schematic design of Mr. Lovegren's circuit which he offers to readers of Radio World and which has given him satisfactory results.

potentiometer shown is essential and is used to obtain the proper negative potential on the grids of the radio frequency amplifier tubes. This should have a resistance of 400 ohms for fine control although 200 ohms will function quite satisfactorily. The bias battery shown is not absolutely necessary, but maximum amplification will be had only with its use. The proper value will be found by experimenting. From 3 to 6 volts will be required for the UV-201 amplifier

tube. Power tubes require as high as 10 volts. For broadcast reception, a brief summary of tuning this circuit is as follows: For a 150 foot aerial, use 50 or 60 turns on antenna inductance with condenser at about 10 on the dial. Set coupling at maximum; use 50 turns on primary; set secondary condenser between 35 and 45 and the feed-back condenser about midway. The rest of the tuning is easy. Send RADIO WORLD your hook-up.

IN response to RADIO WORLD's request for any interesting constructive work in radio that might have been perfected by its readers, Mr. F. W. Lovegren, Box 649, Virginia, Minnesota, sends the accompanying circuit which he has been using for some weeks and which, he declares, is hard to equal. "This hook-up," writes Mr. Lovegren, "is not original, but is the Radio Corporation of America circuit with changes."

This circuit, he further declares, is very desirable for the following reasons:

- 1.—It gets all the stations.
- 2.—It is extremely selective.
- 3.—It diminishes static considerably.
- 4.—It does not radiate.

"For day time receiving," writes Mr. Lovegren, "I have heard WJAP, WWJ, WLAG, WBAH, WOC, CJCG and several others loud enough to be audible half a block from the Magnavox. Using no antenna but simply the usual ground connection, I have heard WSB, WHB, WOR, WDAP, KYW, and others too numerous to mention, loud enough, without exaggerating, to be audible a block away. I need not mention what it will do using the regular aerial."

Description of the circuit is as follows:

The antenna inductance consists of 100 turns of No. 20 or No. 22 wound on a 3 1/2 inch tube, tapped at every 10 turns. The condenser may be either used in shunt, as illustrated, or may be in series with the antenna. No condenser is necessary across primary of the variocoupler, the tuning being done by the secondary condenser and the coupling. Regeneration in this circuit is accomplished by an .00025 mfd., variable condenser which is inserted between the plate of the detector and primary of coupler.

This is an excellent means of controlling regeneration. It will be found that little will be required in this circuit. The detector is not critical in adjustment, therefore no vernier rheostat for the filament or potentiometer, for fine control of plate voltage, are necessary. The

\$2,100 Radio Set Auctioned for \$175

(C) Kadel & Herbert

Here is a photograph of Sterling G. Sears and a United States submarine-chaser radio-set, valued at \$2,100 which he purchased for \$175. This is one of the finest receiving and sending sets made. Recently, the Navy called for sealed bids on this set and Mr. Sears's bid of \$175 was accepted. On the extreme left may be seen the power-panel for generator-control filament and plate supply. Next to this is the transmitting unit. Note the multiple-switch tuning section for antennae adjustment and the vernier helix. In the same cabinet with the transmitting unit is the receiving unit which covers a wave-length range from 150 to 600 meters and, also, two stages of audio-frequency amplification. In the cabinet on the extreme right are three additional stages of amplification.

PHANTOM-CIRCUIT

BUILD YOUR OWN. This marvel of mystery, using no aerial, no loop, no ground, brings in music instead of static showers. We consistently hear concerts on Magnavox, from stations 550 miles distant, audible 100 feet from horn. The simplicity of this set will surprise you. No radio frequency. Complete instructions with photo of circuit sent prepaid for 80c.

Broadcasting Still Grows

Fifteen New Stations Bring Total Up to 565

SOME pessimists predicted that broadcasting would begin to drop off in this, the second, year of radio; but to-day there are 565 stations using the 360-meter wave and 15 Class-B stations operating on the new 400-meter wave, assigned to the larger stations giving high-class programs. There is no indication that this means of disseminating education, news, music and many other forms of entertainment will cease; on the other hand, it seems to be growing, and continues to be one of the most popular American pastimes. With broadcasting as general as it is, stations now operating in every state, the popularity of radio, with the listeners-in, at least, is assured, and initiated neophytes join the numberless throng daily.

Last week fourteen new stations took up broadcasting on 360-meter in as many states. One—the Atlanta "Constitution"—joins the elite class of B stations on the 400-meter wave.

Supplemental List of Limited Commercial or Broadcasting Stations on 360 Meters.

WQAP—American Radio Co., Lincoln, Neb., 500 watts.

WDAG—Apollo Theatre, Belvidere, Ill., 20 watts.

WQAA—Horace A. Beale, Jr., Parkersburg, Pa., 500 watts.

KFBS—Chronicle News & Gas & Electric Supply Co., Trinidad, Colo., 150 watts.

KFCH—Electric Service Station, Billings, Mont., 10 watts.

WOAD—Friday Battery & Electric Co., Sigourney, Iowa, 50 watts.

WNAM—Ideal Apparatus Co., Evansville, Ind., 500 watts.

WGAK—Macon Electric Co., Macon, Ga., 50 watts.

WOAC—Maus Radio Co., Lima, O., 100 watts.

KYG—Radio Service Bureau, Inc., Portland, Ore., 100 watts.

WNAR—C. C. Rhodes, Butler, Mo., 200 watts.

WNAN—Syracuse Radio Telephone Co., Syracuse, N. Y., 250 watts.

WOAB—Valley Radio, Grand Forks, N. D.

WWAX—Worman Bros., Laredo, Texas, 100 watts.

Limited Commercial Class-B Station, 400 Meters.

WGM—Atlanta "Constitution," Atlanta, Ga., 500 watts.

List of Radio Stations Published

AN index to commercial and government radio stations of the United States has just been issued by the Department of Commerce, and is available to the public for fifteen cents at the office of the Superintendent of Documents at the Government Printing Office, Washington, D. C. It gives complete lists of all commercial and government stations, both on land and sea, licensed up to June 30, 1922, including the broadcasting stations. The list of amateur stations is still on press, but will soon be available for distribution by the Superintendent of Documents at about 25 cents a copy.

College Courses in Radio

A HOME course in radio is being given by the extension department of the University of California. The course has been prepared in a style that can be easily understood by the average broadcasting fan. This is not the first home study radio course, however. Last year the University of Wisconsin—one of the first educational institutions to popularize radio—prepared an excellent popular treatise on radio which they distributed at nominal cost to residents of the state.

RADIO PANELS

High dielectric resistance;
6" x 24" \$1.90
8" x 24" 1.25
12" x 24" 1.75
Manufacturers' special sizes solicited. Cuts easily with wood-working tools.

PAGESON COMPANY
Agents wanted. Merchants Station, St. Louis, Mo.

Spirola HIGH GRADE CABINET LOUD SPEAKERS

Do not be deceived by our low prices. SPIROLAS are not cheap instruments made to sell at a low price. They are rather a remarkable development made possible by the invention of the SPIRAL tone chamber (patent pending), which not only allows us to market a cabinet instrument of the highest grade in every respect at an almost sensational price, but gives many exclusive advantages over the common cabinet type speaker, which is nothing but an ordinary horn enclosed in a cabinet—great compactness for a full-sized tone chamber and a really complete elimination of metallic "horn" noises. SPIROLAS are especially recommended to music lovers who can appreciate an absolutely pure, natural tone.

We make a complete line—of equally high-class construction throughout, with fine hand-rubbed finishes. ALL SPIROLAS ARE SOLD UNDER ABSOLUTE MONEYBACK GUARANTEE—ten days to see and try them for yourself.

SPIROLA CONCERT—Complete with special, powerful built-in unit and cord ready to hook up in place of phones, beautiful mahogany or oak finish, bronzed throat. \$12.50

SPIROLA DELUXE—New, improved duplex type for use with your headset, two complete speakers in one, eliminating the usual interference between phones. \$4.85

Satin black finish, nickel plated fittings, otherwise same \$3.85 as DELUXE

We also make the DELUXE and black finish types for use with a single loud speaker unit. In ordering state whether for use with headset or unit.

At dealers or postpaid (C. O. D. if preferred).

Radio Talks by Naval Officials

THROUGH the co-operation of the Naval Communication Service and the American Marine Association radio talks will be broadcasted by representatives of the Navy Department in Washington from November 8 to 11.

A large radio receiving-set and loud-speaker was installed at the Grand Central Palace, New York, by the naval radio experts, and the talks broadcast from Washington are available Wednesday, Thursday, Friday and Saturday evenings of this week for those attending The American Marine Association Show. The broadcasting will be done from NAA, Arlington, over the new radiophone set at 2050 meters.

The speakers selected include Admiral Coontz, chief of operations; Rear-Admiral Robison, engineering; Rear-Admiral Washington, navigation; Rear-Admiral Moffett, aeronautics; Captain McNamee and Captain Overstreet. It is understood that each of the speakers will talk on subjects under his direction in the Navy Department in connection with sea transportation.

The United States Naval Band, well known to those who pick up NOF, will play several selections each evening during the latter part of the exposition week.

At this, the second American Marine Exposition, the Department of Commerce has radio exhibits in connection with the work in the Light-House Service, the Bureau of Standards and the Radio Section, an inspector being detailed to explain the work of the department to those interested. Exhibits are also planned by the Navy and Shipping Board.

Radio As You Ride

ABOUT the first thing the radio novice learns is that to operate his receiving set he requires a long antenna suspended high in air and a "ground" connection to establish an electrical circuit through the surface of the earth, says Henry Smith Williams, in "The American," New York. The establishment of this antenna system is much the most difficult part of the work of installing a radio receiver. So it is rather hard to get away from the idea that it is an essential part of the radio mechanism. Yet in reality it is quite feasible to do away with this cumbersome apparatus altogether, provided certain other conditions are met. These alternative conditions involve merely the making of a receiving apparatus that is more sensitive than the one with which the novice usually starts.

In a word, it is necessary to have an electron tube (triode) amplifier, preferably more than one of them.

With one or more such tubes installed before the "detector" tube we obtain what is called radio-frequency amplification. Messages that would otherwise be too faint for recognition are amplified to the stage of audibility, and radio messages of ordinary intensity may be received on a small loop aerial, no cumbersome antenna being required.

Almost any coil of wire will serve for such a loop aerial. Five-inch coils have been used, but ordinarily it is expedient to use a loop of about two or three feet in diameter. No "ground" connection is required. The apparatus is self-sufficient.

The convenience of such an apparatus, which can be installed on a card table in your drawing room or office, with no bother about wires up on the roof or water pipe "ground" connections, is obvious. Moreover, you may adjust the entire apparatus on your automobile if you wish and "listen in" as you ride anywhere within a hundred miles or so of the broadcasting station.

Fifty-two issues for \$6.00. Sub. Department, Radio World, 1493 Broadway, N. Y. C.

Radio Wonders

ATTENDANCE at our meeting house Was limited to one starved mouse; Until the thought struck Deacon Snow To make us good by radio. The folks they all turned out for fair To get religion from the air; But Deacon must have crossed his wire— 'Cause that dern box up in the choir Yelled out, "Babe Ruth is now at bat, Dusted the plate off with his hat. Strike one—the crowd in great suspense; Busted a homer to the fence."

A fool kid whooped right out, "Eeyow!" And Deacon mopped a clammy brow; But our folks 'ten church as they should, Since science came to make us good.
—M. H. R. in "Louisville Courier-Journal"

Mr. Ford Issues a Denial

A report was widely published, last week, that Henry Ford intended to establish 400 broadcasting stations throughout the United States. Following our rule to run down the source of such a statement, in the interests of accuracy, RADIO WORLD wrote Mr. Ford for further information. His letter, which follows, is self-explanatory:

EDITOR, RADIO WORLD:—In reply to the query contained in your letter of October 23rd, the writer wishes to advise that there is no truth in the report.—Frank Campsall, Assistant Secretary to Henry Ford.

Mary, Up to Date

MARY had a radio set, With nickel-plated trimmin', She took it everywhere she went, And even when in swimmin'.

She turned the little knobs about, Until they tuned three-sixty, And listened in on broadcasting, With a smile that was quite nifty.

Now, Mary had a beau, y' know, A lad who pounded brass, He taught her all the code there was, Till she was quite the class.

So now she turns the knobs again, But to a different place, She listens on two hundred now, And keeps up with the pace.

And so it came about one night, When Joe was on the air, And Mary had her license, too, A parson tied the pair.
—"The Modulator."

An Audiotron Record

Editor, RADIO WORLD:—How is this for a record on an old audiotron (double filament) and two-variometers (regenerative receiver). Tune out WDAP, tune in KDYL, "Salt Lake Telegram," Salt Lake City, Utah, 1,320 miles. Tune out KYW, tune in CJCG, "Manitoba Free Press," Winnipeg, Canada, 750 miles. Have 2-step amplifier with loud-speaker. The aerial I have is about 54 feet long, 11 feet high at one end and 18 feet high at the lead-in end; 3-wire inverted-L type, No. 18 bell wire.

I have tuned nearly all the eastern and southern stations with one tube.

I think it is the way the set is wired and the sensitive detector that has a lot to do with tuning DX. 73-O.M.—Eugene L. Mueller, 8012 Kimbark Avenue, Chicago.

I Want a Radio Worker In Each Community To Work For Me

My work fits in nicely for those men and women who have spare hours or full time at home and wish to earn from \$5.00 to \$40.00 weekly, depending on time you devote to it. It is not radio work, but I believe anyone energetic enough to interest themselves in Radio will make an excellent "TANGLEY BRANCH MANAGER," to operate a branch for us in their home. Pleasant, easy work, no canvassing, immediate profits. No experience or special talents necessary. We furnish complete outfit, train you for the work, and assist you in building up a business you will be proud of. Don't wait until another grasps this offer, write today for literature, and make your spare hours earn.

TANGLEY CO., 187 Main, Muscatine, Iowa

Examine Your Set!

THE best set goes wrong at times. Often the fault appears without warning. More often than not the first time the owner realizes the trouble is when he opens up for the evening's work. Then in an attempt to find the trouble quickly the most evident spots are overlooked, says "The Globe," New York.

Although an A or B battery decreases in potential rapidly after passing a certain point in its discharge they do not as a rule lose their charge over night. But such a thing has happened. Usually the destruction is wrought by a wire which, dropping loose from its terminals, falls across the two sides of a circuit leading from the battery. If this occurs to the A battery circuit the falling wire must be large in size or the contact poor, otherwise the current will heat the wire to its melting point. But the current capacity of the B battery is rated in milliamperes, and the only catastrophe that might take place with a short circuit on this line is a full and complete wrecking of the cells. A small pocket voltmeter reading up to at least 50 volts is desirable for checking these possible faults. •

Because the antenna seems such a simple fool-proof affair it is usually excluded from consideration when trouble shooting. But nowadays, with so many antennae offering alluring targets for youngsters, an inspection of the wires and lead-in is well worth the bother, for a grounded aerial is almost as good as no aerial at all, which to most set owners is the limit of worthlessness.

Aerials may be easily grounded by stray loops of wire which, thrown carelessly or by intent across the strands, touch the guys or metal poles. Lead-ins may be grounded in the same way. It sometimes happens that the lightning arrester gap drops together effectually producing a one-way circuit to the ground.

It is only by following the radio installation from end to end that these hidden uncommon faults may be tracked down.

Radio Delivers Delayed Letter

WHEN a belated telegram addressed to a passenger on the Buffalo limited of the Lackawanna Railroad reached the station master's office at Hoboken, New Jersey, a few night ago, radio was called into play to page the passenger and to deliver the message to him. The train at the time was making fifty miles an hour, but the reception was clear and distinct.

DO YOU USE A CRYSTAL DETECTOR? ARE YOU MAKING A CRYSTAL RECEIVER? Increase the efficiency of your crystal detector 1000 per cent by using a "PT" Ultra-Sensitive Contact. Of special gauge and alloy; makes and holds a quick, ultra-sensitive, stable, adjustment. Endorsed by RADIO WORLD. Using galena, you may pound panel or table without disturbing sensitivity in slightest. Proved practical on shipboard by an oldtime Marconi operator. Using a "PT" Contact on galena, Arlington (NAA) was brought in clear at 3,300 miles (below the Equator); and Arlington came in loud at 2,200 miles (off Dutch Guiana). In both instances, nearby ships using vacuum tubes were unable even to hear NAA. As to stability, Cape May (WCY) was worked over 1,000 miles, sending right through crystal with 2 KW spark, without affecting detector's adjustment. Replace your insensitive unstable spring or catwhisker with a Contact which will hold its adjustment in addition to giving louder signals and music. Indispensable for use in your crystal set, regardless of make. A novice can install. "PT" ULTRA-SENSITIVE DETECTOR CONTACT, with instructions, twenty-five cents, coin or M. O. "PT" CRYSTAL CONTACT CO., Box 1641, Boston & Massachusetts.

Broadcast Bill's Radiolays

By William E. Douglass

FOUR years ago Ol' Kaiser Bill got scared an' yelled, "Enough," because he said the enemy wuz treatin' him too rough. An' so in Brussels Sprouts each year we aim to celebrate November the eleventh as a most important date. It seems like it's been forty years instead of only four since we wuz in the Argonne wishin' we could end the war. In June of nineteen eighteen I wuz down along the Marne so blue an' doggone homesick that I didn't give a darn what happened. Then the orders came fer us to go up front an' bein' sorter reckless that's the time I pulled the stunt of bringin' in some Heinies an' I got my D. S. C. It made

the home-folks here in town all mighty proud of me—that's why the Armistice Parade is run by Private Bill. I've run it now fer four years an' I guess I always will. As long as I've been doin' it things never have gone blooey. Sometimes I think I'm smart enough to be a second Lieutie. Now take fer instance this year, my scheme worked out purty nice, it didn't cost me very much but it was worth the price. I had my radio hooked up in the reviewing stand an' then "picked up" a station where a Military Band played patriotic music. I left Min to watch the set; the celebration this year wuz the best one we've had yet. I had the Brussels Sprouts police head up the big parade. Yep, both of them right in the front, no need to be afraid of traffic interferin' when we're marching down

the street. I tell you in their uniforms our cops look pretty neat. Then come the Golden Cornet Band, they made a lot of noise an' marchin' right behind them wuz the Hook an' Ladder Boys; an' then some flivvers all dolled up in red an' white an' blue—Chuck Walker had to butt in here just 'cause his car wuz new. An' then I an' my buddies finished up the grand procession. Our luck wuz breakin' mighty good to make a fine impression, fer just as we got up to where my wireless set wuz playin' we heard Star Spangled Banner an' it goes without my sayin', I had the boys halt on the spot an' yelled, "Comp'ny attention!" Believe me this here Radio's a wonderful invention.

(Copyright 1922, Westinghouse Electric & Manufacturing Company.)

How to Make a Decremeter

Figure 1—This diagram may be cut out and used as a decremeter.

IN RADIO WORLD, No. 32, dated November 44, there was published, complete, an article of first value to radioists entitled, "Wave Meter for Amateur Operators," describing how to construct the device which enables one to adjust his set and comply with the law. This article was prepared by the United States Bureau of Standards experts. Frequently it is necessary to employ a decremeter with a wave meter.

It is possible to make a decremeter out of a wave meter by placing a suitable scale on the variable condenser. For a wave meter

having a condenser with semi-circular plates or any condenser such that the graph of its capacity against its setting is a straight line, the capacity being very small at zero setting, it can be shown that the decremeter scale to be used is one in which the graduations vary as the logarithm of the angle of rotation. Such a scale, designed for a semi-circular plate condenser, is shown in Figure 1. This scale may be copied, or cut, from this issue of RADIO WORLD and trimmed to fit the dimensions of the condenser dial with which it is to be used. It may be made stationary with a moving pointer traveling over it, or it may be mounted on a dial rotating under a fixed pointer. At the setting corresponding to maximum capacity the scale reading should be zero. Since the scales of most condensers read counter-clockwise, this arrangement usually places the decremeter scale in the unused space opposite the capacity scale.

A measurement of decrement is made by first observing the current squared at resonance, then reading the decremeter scale at the settings on either side of resonance where the current squared has one-half its value at resonance. The scale is so constructed that the difference between these two readings is equal to the decrement of the transmitting circuit plus the decrement of the wave meter itself. It is then necessary to subtract the wave meter decrement from the total just obtained. The decrement of the wave meter is determined as follows: the wave meter is coupled and tuned to a source of unmodulated continuous waves. The sum is measured as just described. Since the waves are continuous, the decrement of the waves is zero and the result obtained is the decrement of the wave meter alone.

From determinations of the decrement of the wave meter made at different points on the scale, the calibration curve of decrement plotted against condenser setting is obtained. The conditions necessary to permit the use of this scale in the manner described are as follows:

1. The condenser must have semi-circular plates. Condensers with plates of a different pattern will have different decrement scales just as they have different capacity calibrations.
2. It must be remembered that only when resonance is indicated by a current-square meter is the deflection to be reduced to one-half its maximum value in detuning to either side of resonance. If a milliammeter is used, the reading must be reduced not to one-half its maximum value, but to the maximum value divided by the square root of 2 or to 0.71 of the maximum value.
3. The generator must have an output sufficiently large that the coupling employed may be loose enough to prevent any considerable reaction of the wave meter on the generator.
4. Neither the generator nor its coupling with the wave meter must be changed during the measurement of decrement.

Field Sets Used by U. S. Navy

(C. Underwood & Underwood, N. Y.)

Here is a transmitting set used exclusively by the United States Navy. It should be of interest to every radioist. It is different from sets in ordinary use in this respect: It is made so that it fits in a suitcase, making it possible to carry it ashore for land duty. In the left of the photograph is the transmitter with its compact inductance coils, making it possible for the operator to broadcast on a wave-length fixed for any particular purpose. With radio transmitters, high voltage must be secured to apply to the necessary tubes. In this case, a special machine is used as shown at the right to supply this power.

"He is rich," said Confucius, who knows when he has enough! Would you find the richest man? Look for the owner of a Grebe Receiver.

Doctor Mu.

The whole world is at your fireside when you own a Grebe Receiver.

Ten years of radio manufacturing experience has taught us the importance of simplicity. Recommended by most good dealers because they know the shortcomings of ordinary apparatus.

Ask your dealer for a demonstration. Get your copy of "Musings of Dr. Mu"—the story of the development of the Perfect Receiver.

Radio Devices You Should Understand

THE lower picture shows Elman B. Myers, inventor of the Myers vacuum tube, photographed with his new radio-receiver. Mr. Myers is using the well-known circuit of radio frequency—three stages of radio frequency before the detector tube with which to amplify weak signals. When weak signals are amplified after having surged their way through the three amplifying tubes, they are then sent through the detector tube for rectification. The detector tube rectifies the radio frequency to audio frequency, making it possible for the signal to be heard in the telephones. After the detector tube, Mr. Myers employs three more

(C. Kadel & Herbert)

Spark transmitter and leyden-jar condenser

(C. International News Reel)

Elman B. Myers with apparatus for three stages of radio- and audio-frequency.

stages of audio amplifiers. With 3 radio-frequency amplifiers, 1 detector, and 3 audio-frequency amplifiers. Mr. Myers should hear everything.

The radio transmitter shown in the (upper) larger photograph is one of the old-type sets that made its appearance about six years ago. The explanation of the numbers is as follows: 1, The pair of meters for registering the motor-generator. 2, The quenched-spark gap. 3, The power transformer. 4, The leyden jars, better known as the condensers. 5, The hot-wire ammeter.

The Counterpoise

Its Advantage as a Complete Reducing Agent in the Resistance of the Antenna Fully Explained

By *Frederick J. Rumford, E.E., R.E.,*

THE counterpoise is a sadly neglected hook-up. Few radioists have experimented with the counterpoise since Sir Oliver Lodge, as far back as 1890 made a number of experiments.

The advantage of the counterpoise for the receiving station is a general complete reduction of the resistance of the antenna, or aerial, which with this reduction would result in a decided decrease or lowering of the decrement of the circuit, or circuits, in use and would increase greatly the circuit, or circuits, selectivity which would also increase the intensity four-fold or more.

The writer in one particular instance of experimenting found that with one of his many experimental antennas and counterpoises he had decreased the resistance of the circuit from about 50 ohms down to about 8 ohms when he had used the counterpoise instead of the usual water-pipe ground connection. Radio fans who live where the earth is very dry should try one of the counterpoise connections illustrated in the four figures accompanying this

article; for the earth being dry, it functions very poorly as a ground conductor of radio waves.

Figure 1 represents the antenna and the counterpoise as erected—when the antenna is on the roof—on the usual masts or poles. Should the antenna be mounted on poles about 12 feet from the roof top with the counterpoise exactly 6 feet below it, the method of mounting is as follows: The antenna should be either or 1 or 2 wires—No. 14 bare copper or any other good aerial wire—from 60 to 100 or 150 feet long, spaced about 3 feet apart. That is, if 2 wires are used with the usual insulators at each end, the counterpoise should be 6 feet under the antenna. If possible, it should be several feet longer than the aerial and spaced about 4 feet apart, if 2 wires are used. The method explained above is for the fan who hasn't the space to erect his aerial on mast from the ground up; who, by necessity, must have his antenna on the roof.

Figure 2 shows another method of making an efficient antenna counter-

poise. This method is for the fan who has plenty of room to erect his antenna on masts implanted in the ground. This counterpoise may be of either 1 or 2 strands of No. 14 bare copper or any other good aerial wire. It should be at least 30 feet high from the ground's surface and either 60, or 100, or 150 feet long. If 2 wires are used, they should be spaced from 2 to 3 feet apart and the counterpoise should be mounted about 6 feet from the ground. If possible, it should be several feet longer than the antenna. At the double end, these wires should be spaced at least 5 feet apart. This type counterpoise is known as the V anti-ground conductor. If this type is chosen, the writer feels certain that the prospective builder will have no reason to be disappointed.

Figure 3 shows another view of the antenna counterpoise which may be erected where one end of the antenna and the counterpoise may be connected to the attic or the weather-head of the house by means of suitable insulators, and a pole of 30 or 40 feet high and 60, or 100, or 150 feet from the house. The antenna in this particular instance, was 1 No. 14 bare copper, or any other efficient aerial wire, with its respective insulators. At either end, the counterpoise is of 2 wires spaced about 3 feet apart and, if possible, several feet long. The antenna should be erected about 7 feet from the ground so as to not interfere with anything passing beneath it. It is insulated at either end with the usual insulators. This hook-up has proved

Figure 1—The antenna and counterpoise as erected when the antenna is on the roof of the house. Suggested by Frederick J. Rumford. Drawn by S. Newman.

Figure 2—Another method of erecting an efficient antenna counterpoise. This method is for the fan who has plenty of room. Suggested by Frederick J. Rumford. Drawn by S. Newman.

Radio Don'ts

- DON'T** hook-up a pair of poor phones with a good receiver.
- Don't** drop the ear pieces on the floor. Keep the magnetism intact.
- Don't** take the covers or caps off just to see the inside. Leave well enough alone.
- Don't** add a loud-speaker to any type of crystal receiver.
- Don't** expect an amplifying horn to produce the same results as a loud-speaker.
- Don't** connect the house lighting-current to your tubes.
- Don't** forget that rheostats are used to light the filaments.
- Don't** apply too much current to the filament.
- Don't** use plate batteries to light the filament.
- Don't** expect too much from a crystal receiver.
- Don't** touch the mineral in the detector with your fingers.
- Don't** use lead or solder in mounting the mineral.
- Don't** be afraid to occasionally clean the crystal with alcohol.
- Don't** forget that a fixed adjustment on a mineral detector will not hold its sensitivity permanently.
- Don't** leave your tickler coil at maximum with your tube oscillating and generating radio-waves.
- Don't** insert condensers in series with the ground and expect to increase your wave length.

Changing Inductance and Capacity

By Fred. Chas. Ehlert

THERE are various methods of changing inductance in a circuit. A straight wire has very little inductance. Make a coil of the same wire and the inductance is considerably increased. The coil may be made either by winding it smoothly over a form, such as a broomstick, or by winding it spirally in the same place. Electrician's tape may be purchased in a roll. The inductance of a coil is changed by changing the number of turns of the coil in the circuit.

There are, also, various methods of changing the capacity in a circuit. A second method is by changing the capacity of a single condenser. This is

done by having both sets of plates that make up the condenser movable in respect to each other. When every part of the plates in one set is opposite the plates in the other, the capacity is the greatest. Capacity is made smaller by having only a part of each plate in one set opposite the plates in the other.

The inductance and capacity needed in an oscillating circuit is contained in the antenna of a radio transmitter. The antenna of radio set is that part of the set which radiates the energy by setting up the waves in the ether as explained. The wires making up the antenna give both the capacity and inductance.

(Continued from preceding page) very practical, but it is mostly for the fan who has the space to span his wires any number of feet from the house.

Figure 4 is the antenna counterpoise the writer experimented with and which he found efficient, reliable, and practical. This antenna counterpoise is intended for fans who have any amount of space at hand in order to erect it complete. The instructions:

Erect 2 masts, or poles, of some seasoned wood; or, better still, erect 2 steel towers. These should be from 30 to 60 feet high and spaced 60, or 100,

or 150 feet apart, to suit the convenience of the prospective builder. One wire, either No. 14 bare copper or any other efficient aerial wire, should be stretched from mast to mast with suitable insulators at either end. The counterpoise is then erected about 7 or 8 feet from the surface of the ground. It should be several feet longer, if possible, than the antenna and should have suitable insulators at either end for perfect insulation. It must be placed sufficiently high from the ground so as not to interfere with anything passing under it.

The following are necessary in the

erecting of any of the above antennas or counterpoises.

They must be thoroughly insulated from the ground.

The lead-ins must be thoroughly insulated from the ground.

The counterpoise lead-in connected with the ground is usually connected up on the receiving set.

The writer feels certain that the builder will not meet any great difficulty in erecting one of the counterpoises described, but if he does, I will answer gladly any questions that he may ask, if accompanied by a self-addressed, stamped envelope.

Figure 3—The antenna counterpoise so erected that one end of the antenna and the counterpoise may be connected to the attic of the weather-head of the house by means of suitable insulators. Suggested by Frederick J. Rumford. Drawn by S. Newman.

Figure 4—An antenna counterpoise that was found efficient, reliable and practical. It is for fans who have plenty of space in which to operate. Suggested by Frederick J. Rumford. Drawn by S. Newman.

The Importance of Understanding and Testing Radio Apparatus

By C. White, Consulting Engineer

Radio testing apparatus used by Mr. C. White in the tests described in this article.

THE general practice of scientific-laboratory testing and research has been neglected in the radio field. While it is quite true that certain manufacturers have taken special interest in the practical trying-out and testing-station work conducted by various scientific and semi-scientific journals, still there are comparatively few who have actually put themselves to the additional trouble and expense to have a definite line of scientific experimenting on their apparatus. Although an actual try-out will bring to light many of the serious inherent troubles in a radio receiver, yet, owing to the uncertainty of varying atmospheric conditions, it is utterly impossible to determine the absolute or definite relative value accurately by such methods.

We are about to enter upon the second year of our unusual radiophone popularity, and it would do well for many of us to think over the problems that must be solved if the wireless science is going to progress. And the most important problem we are facing for solution is the development of more supersensitive receivers. From developments and inventions brought forth during the past year we do know that, by means of more sensitive receiving apparatus, we could be able

to receive from stations (radiophone) at least 5,000 miles or more distant. At present such a feat—if, indeed, it could be fully realized—would be considered a miracle.

Research is more than testing for defects in goods already manufactured; it is the searching out of new and fertile fields for development on the border line of the unknown. For the past year I have been trying out—by means of definite and well-founded scientific principles—the comparative values of the different amateur receiving sets on the market. To receive from a certain station is not a very good test for a receiver because, perhaps, reception was due to some freak atmospheric condition, under which even an ordinary crystal set is said to produce marvels. Not even the repeated reception from a certain distant station can be taken as a good basis of judgment, for the quality of the received signal will largely depend on the amount of power received and the modulation of the transmitter, all of which is quite variable from day to day. So, in conducting this work, it was very necessary to construct within the narrow confines of our laboratory a small sending-station which we could absolutely regulate and control to give us various amounts of power.

In other words, we tested out the various receivers on what might be called a phantom signal, and by carefully arranging and shielding the various pieces of apparatus used we could quite effectively try out our theories and delve into the troubles in present receivers and at the same time compare them with newly developed circuits of our own.

In Figure 1 is illustrated two types of oscillators used in our receiving experiments. The one shown on the right used honeycomb coils for tuning inductances, while the apparatus on the left makes use of ordinary inductance coils so wound as to cut down to a minimum point distributed capacity. The former is a better oscillator for short waves, especially since it is wired up for two types of oscillating circuits, thereby allowing close and quick check operations by means of two tumbler switches. We obtain an artificial modulation by placing the secondary of a small modulating transformer (audio-transformer) in series with the plate potential supply (the B battery). The primary of this transformer is fed from a small 780-cycle alternator. So, theoretically, all we do is to impose a 780-cycle audible note on the high radio-frequency carrier wave. The output terminals of our oscillator are

Do Not Force Power Tubes

By Peter Gray

IT is unwise to overload or force a radio-tube power-tube, as its operating life will be menaced. It is a better plan and more economical to operate two tubes in parallel than it is to force one tube to deliver a power output far in excess of its rating. Economy will result from burning tubes slightly below normal brightness—to double the filament emission will reduce the operating life of the tube one-half. Burning the tube at 95 per cent of its normal brightness will multiply its life fourfold.

When first testing the circuit, or when the set has not been operated for some time, cut down all voltages to one-third of the normal voltage. This will greatly reduce the possibility of burning out the tube through a wrong connection which has been overlooked. The fault will then instantly be detected before the damage is done.

In a radiotelephone transmitting circuit a modulator tube is employed and a buzzer substituted frequently for the microphone to send out interrupted continuous waves. This imposes voltage strains on the oscillator tube.

Important Insulation Necessary

IN powerful C-W transmitting sets, the circuits should be so arranged that the center tap on the filament coil and, also, the negative lead of the direct-current high-voltage source are both at ground potential relative to high-frequency potentials in order to insure safety. Great care should be taken to thoroughly insulate the grid and plate leads to the tube and the coil sections connected to these leads or to any apparatus in them.

He Built This Set for \$21

(C. Kadel & Herbert)

The above is a photograph of Charles Murphy, radio student at Fordham University, New York, completing a regenerative receiver with one stage of amplification, which cost him \$21. With this set Mr. Murphy can hear the distant stations. By means of the Armstrong circuit which is produced by the aid of the variometer in the plate circuit feeding back the energy into the grid circuit, and a condenser, he is able to eliminate the taps on the coupler of this receiver. For a detector tube, he is using an old audiotron-tube and a V-T No. 1 as an amplifier. 1 is the amplifier case containing the detector tube and the amplifier. 2 is the detector tube. 3 is the variometer in the plate circuit. 4 is the variable condenser. 5 is the coupler, with its peculiar winding. 6 shows the method of soldering a connection in the amplifier. 7 is the amplifier tube or the V-T1. These comprise the complete receiver.

(Continued from preceding page) fed through a mutual inductance coupling, which is nothing more than a specially constructed vario-coupler, to the antennae and ground terminals of the receiving set to be tested. By this method we not only control the frequency of the modulating circuit, but we can carefully control the relative amplitude of both the audio-wave and the radio-frequency carrier wave. Therefore it is quite easy for us to actually assimilate a nearby, or distant, station by so doing. The brief outline of this method clearly shows the theory behind the operations, but there are many practical points and considerations that must be fully taken into account before a good and authoritative comparison may be materialized.

First, we must carefully intershield all of the component apparatus we are employing in the test hook-up. This does not only include a complete shielding of the generators, radio-frequency oscillators and audio-frequency alternators, but all the parts of the oscillator. In addition to this we must place the audio-frequency set in another room to get rid of its noise, and we must carry out the tuning and audibility test on the receiver in a specially screened-off corner of the laboratory.

After all apparatus for generating the phantom signals are adjusted and set in operation the tester must crawl into his screened-off cage with the set that is under consideration. Generally a well-planned selectivity test is carried out to determine the relative amount of selectivity by means of slightly changing the wave-length impressed. Next, the audibility of the volume received is measured by means of an instrument known as the audibility meter; then comes the distortion test. This test is accomplished by photographing the wave-form of the audio-frequency wave as generated by the high-frequency alternator and then photographing the wave-form as received by the phones. The actual photographing of this wave is done by the aid of an oscillograph—an instrument that traces with light the wave shape of an alternating electrical-impulse. It has been proved by practice and experience that a good set, or circuit, may be readily picked out. Not only has it been able to measure volume and sensitivity, but it has been possible to incorporate many important design changes while the set was on test without the long and tiresome method of sitting up for half-a-dozen nights to get a good average of its new performance. Although this method of

testing is by no means fool-proof in operation, manufacturers who lack facilities for such work avail themselves of such service, for it is well understood that many improvements can be made on the best outfits

While I have only outlined the phantom reception test, there are many more tests—resistance, inductance, capacity, and leakage tests—that lack the complexity of the one previously outlined, yet they are quite essential and important. If we intend to perfect radio for the home, just as the kodak has been simplified and perfected, we must carry on more aggressive research. It is not enough to hitch a set up to an aerial and turn the dial until a sound is heard. We must do more. We must investigate relatively the volume and the tone quality of the same. We must try out different types of arrangements and see if the general quality can be improved. The modern radio amateur is quite willing to accept the better grade of goods, and it will not be long before he not only will request a better scientific instrument for his home, but he will demand it. Since we are facing National Radio Week let us all—manufacturers and amateurs—turn to the right and realize the possibilities of radio for home and business.

Radio Takes on More Wartime Duties

Signal Corps Radio Direction and Range Finders Will Aid in Coast Defense and Extend Distances

By *Carl H. Butman*

(Copyright, 1922)

WASHINGTON, D. C.—The ranges of the shore-defense guns of the United States in all probability will be extended twenty-five miles farther to sea by virtue of a newly developed radio range-finder now being tested on the Atlantic Coast. Previously the maximum range of the great coastal guns was approximately twenty-five miles when visibility was good, but with the perfection of the signal corps radio devices poor visibility is not a handicap, and it is expected that a maximum range of about fifty miles can be reached, provided the guns are elevated high enough to be fired that far. Enemy ships will have to stand farther out at sea to be safe; at least, the fleets will be prevented from anchoring or disembarking troops within fifty miles of our shores in wartime.

Employs Radio, Aviation and Plotting

Three factors make up the essential principles of the new long-range fire control—radio, aviation, and plotting. For the first time in history the post-war developed radio-compass will be employed for a purpose other than to locate stations or give ships their bearings. The use of an airplane equipped with radio for spotting the fall of projectiles is not new, but the unique feature today is the fact that the airplane itself will be out of sight over the target or ship. Without awaiting the fall of sighting shots the observer will send a series of radio signals which

will make it possible on shore to plot the successive positions of the ship and determine its course and speed.

One of the problems of the joint coast artillery and air service maneuvers, now under way off the Virginia Capes, was a test of the new radio fire control devices and a comparison with the old method. A boat visible from the shore will run various courses in an area several miles wide, stretching seaward from Cape Charles and Cape Henry, the master of the vessel keeping an accurate time record of his course and speed. An airplane from Langley Field equipped with radio-sending apparatus will fly out, locate the ship, and remain over it as much as possible by executing the figure 8 in the air. Flying at a height of several thousand feet, calculated to be safe from anti-aircraft fire, this observation plane will send special signals to the shore only when it is exactly over the vessel, continuing to do so until ordered in by the shore stations.

Radio Direction Stations Ashore Get Signals

On shore two radio-compass stations, several miles apart, have been set up and direct lines of communication laid to the batteries. Operating just as when a ship's bearing is furnished these two stations will pick up the signals sent by the observing plane when it is over the target ship. In other words, they will turn their com-

pass coils until the radio signal is received with equal strength in both receivers, then the direction, or angle, from the stations will be read and plotted. With the angles at each station read simultaneously, and the distance apart known accurately, it is a simple problem in trigonometry to locate the position of a ship and its distance from the battery. It is even simpler to plot the location of the ship on a map by laying down the angles from the two stations, extending the lines and noting their intersection. Within a few seconds a second signal comes in, then another; all of which, when carefully plotted and timed, give the course of the moving target and its speed.

Firing at Unseen Targets Miles Away

Firing may or may not be undertaken in the initial test. This does not matter, as it is solely a problem of ordnance and ballistics after the ship's course is plotted. The artillery men do the rest, although they see nothing of their target many miles at sea. The most important feature of the scheme is its adaptability to night operations and in thick or foggy weather. Conditions do not matter so long as the observing plane can find the ship and fly over it. The distance from shore does not matter; but the range may be increased over the old range, limited by visibility from the observing towers, planes, or balloons ashore, by many miles beyond the horizon.

A comparative test made by another plane flying nearer shore will also be made; but as the data this observer can give will be only in the form of estimates as to the bearing, or azimuth, of the vessel, and its distance from Fort Munroe, it is not thought this old method can furnish the plotters with sufficient accurate information to compare with the more exact radio direction finding system.

Coöperating with the board of coast artillery and air service officers conducting the test, Captain G. W. Morris, of the Signal Corps, is in charge of all radio operations during the first tests of the army's new radio direction finder now applied to gunfire.

Among other experiments to be conducted during the week will be tests to determine the extent of interference to radiotelephone and telegraph messages caused by neighboring radio communications in operation.

(Cartoon by Lawrence B. Hinckley)

RADIO ON THE FARM HAS ITS DRAWBACKS

Farmer Dill: "I wonder what kin be wrong with this contraption! Just about this time every night it seems to pick up some very familiar noises."

Operating a Three-Unit Honeycomb Regenerative Receiver

By John Kent

A TYPE of tuning apparatus, operating under the inductance principle, is the honeycomb-coil unit. These coils are single units and are used in conjunction with the adjustable mountings, the coils with the mounting making up the tuning unit. Similar mountings are made for the two-coil unit.

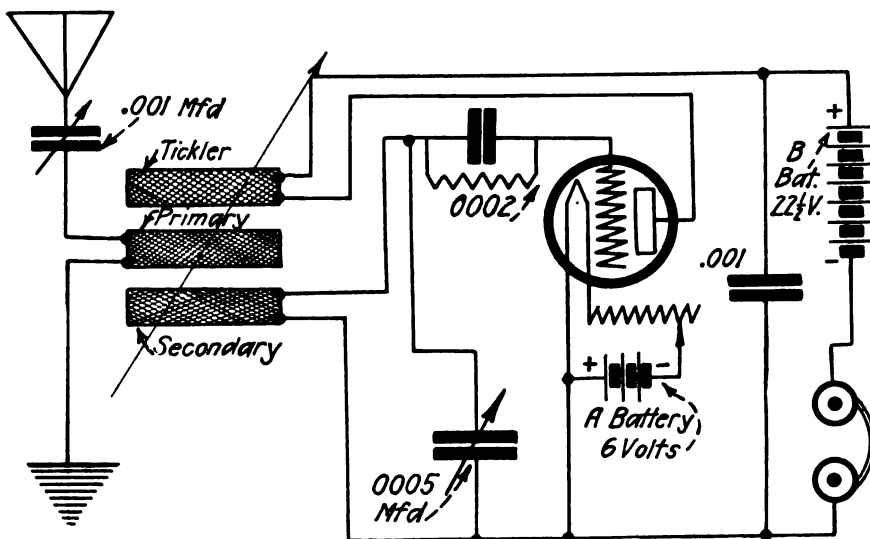

When the honeycomb-coil mounting is used, the same advantage is taken of electrical phenomena as in the case of the vario-coupler and the loose-coupler, that is, oscillatory current flowing through the honeycomb coil, which acts as a primary, creates magnetic lines of force. When flowing through the secondary coil, the lines of force induce a current. As the angle is changed between the two coils, the magnetic lines of force affecting the secondary is varied. Therefore, the angle, or adjustment, of the secondary controls the magnetic lines of force.

Instead of tapping the coils, a number of honeycomb coils must be on hand to be inserted—as the length of the broadcast wave requires. A three-coil schematic diagram is shown herewith, in which the third coil is used in the plate circuit to produce amplification. A table published in RADIO WORLD, No. 32, dated November 4, showing the different coils needed to receive from the various wave lengths.

To operate the set, light the filament of the tube to as near brilliancy as possible, the tickler coil being set at zero. Increase the brilliancy of the tube until the hissing sound is heard in the ear pieces. When this is heard, decrease sufficiently to stop the hissing. Set the coupling at maximum and the primary and tickler at its lowest value. Then, very slowly, vary the secondary coupling from zero to maximum.

If no signals are heard during this operation, change the primary setting five or ten degrees and vary the secondary through its range. Do this until signals are heard. If they are not heard, increase the tickler setting and repeat. When the signal has been heard, adjust the controls for best results, remembering that, in order to obtain selectivity or freedom from interference, the coupling must be decreased considerably to zero. This should be done gradually in order not to lose the signal.

The tickler coil may be increased to best position, but not so far as to oscillate, as oscillation spoils the signals.

Schematic diagram showing how a third coil is used in the plate circuit to produce amplification.

Oscillation becomes a small generator of high-frequency currents. In turn, this current acts as a transmitter causing current to be sent out similar to that of a sending station. Whenever hissing sounds, varying in pitch, are heard, it is a certain sign that some re-

ceiving station nearby is radiating waves because its tickler coil is turned up too far.

When attempting this hook-up, be careful to watch each connection in order to be certain that the right polarities are made.

Radio Laws and Regulations of the United States

THE owner of an amateur radio-transmitting station must obtain a station license before it can be operated if the signals radiated therefrom can be heard in another State; and, also, if such a station is of sufficient power as to cause interference with neighboring licensed stations in the receipt of signals from transmitting stations outside the State. These regulations cover the operation of radio telephone stations as well as radio telegraph stations.

Station licenses can be issued only to citizens of the United States, its territories, and dependencies.

Transmitting stations must be operated under the supervision of a person holding an Operator's License. The party in whose name the station is licensed is responsible for its activities.

Government licenses granted for amateur stations are divided into three classes as follows:

SPECIAL AMATEUR STATIONS known as the "Z" class of stations are usually permitted to transmit on wave lengths up to approximately 375 meters.

GENERAL AMATEUR STATIONS which are permitted to use a power input of 1 kilowatt and which cannot use a wave length in excess of 200 meters.

RESTRICTED AMATEUR STATIONS are those located within five nautical miles of Naval radio stations, and are restricted to 1/2 kilowatt input. These stations also cannot transmit on wave lengths in excess of 200 meters.

EXPERIMENTAL STATIONS, known as the "X" class, and school and university radio stations, known as the "Y" class, are usually allowed greater power and also allowed the use of longer wave lengths at the discretion of the Department of Commerce.

All stations are required to use the minimum amount of power necessary to carry on successful communication. This means that while an amateur station is permitted to use, when the circumstances require, an input of 1 kilowatt, this input should be reduced or other means provided for lowering the antenna energy when communicating with nearby stations, in which case full power is not required.

Prevent Tube Accidents

THE principles of construction and operation in the larger power-tubes are no different from those applying to the smaller ones. Many effects negligible in the smaller

tubes are magnified in the larger tubes, and certain precautions are necessary. Accidents to power tubes and their auxiliary apparatus occur during the period of development of circuits, testing, and adjustment rather than during operation.

The Radio Primer

*For Thousands of Beginners Who
Are Coming into Radio Circles*

Weekly A B C of Radio Facts and Principles Fully and Tersely Explained

By Lynn Brooks

WHAT is capacity? The condition of the earth is constant. This is because it has a limitless capacity. Capacity is an important factor in electrical work, and it is necessary that we have a thorough understanding of what it is. In order to thoroughly understand capacity let us take two metal balls, one twice as large as the other. Put twice as much electricity in the larger ball as in the smaller one. Now, if

Schematic diagram of a condenser and radio circuit. Note the insulator and the conductor with the negative and positive charges.

we connect the two balls by a wire there will be no change of electricity. There can be no difference of potential (voltage) between them, or there would be a transfer of electricity; that is, the two balls have the same potential and it will require twice as much electricity to bring the larger ball to this potential because the larger ball has twice as much capacity as the smaller ball.

* * *

What is the use of capacity?

Capacity is the ability of a body to hold an electric charge. If the body has a large capacity it will take a large amount of electricity to raise its voltage. If it has a small capacity it will take only a small amount of electricity to raise its voltage. Thus capacity deals with two things: First, quantity of electricity; second, voltage.

* * *

How is capacity measured?

Capacity is measured in farads. A body has a capacity of 1 farad if an ampere of current flowing into it for 1 second raises its potential 1 volt. This is such a large unit that it is divided into a million parts and each

one of these parts is called a microfarad.

* * *

How does capacity operate in a receiver?

Instruments that are built to give capacity are called condensers. Condensers are important in a receiving set. A beginner should fully understand capacity as tuning and other methods of employing receivers cannot be successfully accomplished without it.

* * *

How are the condensers made?

Condensers are made of plates or sheets of conducting material separated from each other by a non-conductor. Evidently the more and larger sheets used the greater capacity of the conductor. The closer together sheets are placed the greater the capacity, as the attraction of the opposite electricities is stronger at shorter distances. The capacity also depends on the kind of non-conductor used between the sheets, as the attraction of the opposite electricities is stronger through some kinds of non-conductors than through others.

* * *

What amount of electricity will a condenser hold?

The amount of electricity a condenser will hold depends not only on its capacity, but also on the voltage of the charging current, or charging instrument. There are various kinds of condensers made for various purposes. They are widely used. In using a condenser be careful not to apply a voltage greater than that for which it is built. If you do a spark will pass through the non-conductor between the plates and ruin the condenser.

* * *

What is a variable condenser used with?

A variable condenser is usually connected with an inductance—one of the elements that makes radio possible. The accompanying diagram gives the complete radio circuit of an inductance coil and a variable condenser. Capacity and inductance are the two main elements used in every radio transmitter and receiver. Without them it would be impossible to work.

Radio Hints

Useful Facts for the Beginner
Who Wants to Know

IN using the vacuum-tube receiver it often happens that the filament flickers or fails to light. In such a case it is a good principle to remove the tubes and clean the ends of the contacts. This is done by either a file or sandpaper. Sometimes the jacks are at fault. When this happens attention should be given the connections of the jack.

Before attempting to make changes on the jacks remove all plate-battery connections before making jack adjustments to prevent a short circuit, which may result in the burning out of the vacuum-tube filaments. Should both stages of amplification fail to produce, the trouble may be placed at the B batteries. Sometimes defective tubes cause a majority of other troubles. It is desirable to test the tubes in various combinations; that is, try them in each socket.

* * *

If you are interested in radio and want to receive broadcast concerts don't let lack of technical knowledge deter you. The most marked recent developments of radio have been in making available receiving sets which anybody can operate by following a few simple directions. Operating a complete receiving set, which can be installed in any home, is no more difficult than operating a phonograph.

* * *

The crystal is the very heart of a radio set. On it depends the entire operation. There are many minerals that may be used for the detector, but up to the present time galena is the best that can be obtained. Do not handle the mineral any more than is necessary, as a coating of oil forms on the surface of the mineral, making the signals weak. Sometimes it will cut down the sensitiveness of the crystal and make the detector inoperative.

* * *

When employing the detector-amplifier unit to a receiver it should be placed as close as possible to the receiver in order to avoid long connections. Always make certain that the battery leading from the storage battery and the B battery are connected to their proper terminals, and, also, that the polarities are not reversed.

* * *

A panel mounting does not allow one to experiment with his hook-up and to show his friends how the circuit actually works. But, to the contrary notwithstanding, a panel-mounted receiver is by far the most attractive in appearance and is often better scientifically if shielded from body effects.

Additional Committeemen Named for National Radio Week

It has been a busy week at the headquarters of the Executive Committee of National Radio Week—December 23 to 30 inclusive—the offices of Major J. Andrew White, chairman, 326 Broadway, New York City.

Major White and his staff have been kept pretty well occupied answering the many telegrams and letters of inquiry that have begun to pour in from all parts of the country. The interest in this important radio event is increasing every day, and is spreading rapidly to all parts of the country.

William B. MacNeary, of "The Sunday Call," Newark, New Jersey, has accepted the position of chief of publicity.

Elmer E. Bucher, author of several important works on radio, and sales manager of the Radio Corporation of America, is to be chairman of the Committee on Dealers.

Because of the amount of work attending his regular duties, Kendall Banning, editor of "Popular Radio," found it impossible to take on the extra work required of a member of the Executive Committee. His resignation was reluctantly accepted, and Arthur H. Lynch, editor of "Radio Broadcasting," was appointed to fill the vacancy.

The following men, all important in the wide-spreading field of radio, have written to the Executive Committee, offering their services to make National Radio Week a genuine success from every angle:

Raymond F. Yates, radio editor, "The Mail," New York; Robert S. Wood, radio editor, "The World," New York; E. L. Bragdon, radio editor, "The Globe," New York; William H. Eaton, "Judge," New York; Pierre Boucheron, Radio Corporation of America; E. H. Rice, General Electric Company, Schenectady, New York.

Radioists of Sandusky, Ohio, are planning a program of special radio festivities for the big week.

Among the letters received during the week were the following:

Robert Curtiss, radio editor, "Guardian Magazine," Ashland, Ohio:

"I will do all I can for National Radio Week."

Arthur G. Shirt, Fall River, Mass., magazine writer and newspaper correspondent:

"Hooray for National Radio Week! I am preparing copy about it—its conception, its boosters, its aims—for the New England papers for which I

write. I will let that be my contribution toward making the week a success."

C. White, Cambridge, Mass., consulting engineer in radio and electricity, and one of the chief contributors to RADIO WORLD:

"I am greatly in favor of a National

Radio Week, and think that the subject of more vigorous cooperation on the part of radio manufacturers for active research and testing as outlined in my article in this issue of RADIO WORLD will certainly raise the trade to a higher plane, which is certainly desirable."

Nine Microphones Start First Complete Church Service by Radio to Waiting World

RADIO listeners and their friends in all parts of the United States, Canada, and even on the ocean liners crossing the Atlantic, were part of the congregation of St. Thomas' Episcopal Church, Fifth avenue and 53d street, New York City, on Sunday, November 5, when the entire service—ritual, sermon and singing—was broadcast by radio.

The singing of the choir and congregation, the sermon of Dr. Ernest M. Stires, the organ playing of Dr. T. Tertius Noble and every word and sound throughout the service was picked up by nine microphones placed in different parts of the church, carried by wire to Newark and there sent broadcast for thousands of miles in all directions. This was the first time a complete church service was sent over the world by radio. It is said that even the clinking of coins dropped in the collection plates was heard.

Commenting on this interesting and important radio event, "The Mail," New York, says editorially:

"The sermon preached in a Fifth avenue church was heard by radio in thirty States, besides Canada, Cuba and Mexico.

"This opens possibilities in the religious field similar to the service by the Associated Press and syndicates to the newspapers. The smallest congregation can hear sermons every Sunday from able and eloquent preachers, the music of the best organists and the songs of elaborate choirs. This particular service had the singing conducted by a choir of seventy-five male voices. So well was the sound transmitted that the slightest noise made by people going up the aisle and

taking their seats was heard by the radio receivers.

"In many villages there are now more churches than the community adequately supports. Denominations are struggling along with small congregations unable to pay their preachers adequate salaries. In the rural districts it is not uncommon for a preacher to have several congregations miles apart and alternate the services in their churches.

"With the radio any denomination can have the most elaborate service and costly sermons at slight expense. The home mission boards of the different denominations can arrange radio services. The congregations can gather in the church and maintain their existence without further contributions than enough to keep the church in repair and heated and put in the radio receiving sets.

"Suppose the biblical accounts of the adventures of Moses had stated that the religious services at Mount Sinai were heard in Egypt and Greece and Italy? People of little knowledge and less faith might have called that an impossible miracle."

Tube Suspension

THE life of radiotron power-tubes may be prolonged by mounting them in the proper position. Radiotrons No. 13248, type UV-202 and No. 13247, type UV-203 should be operated in a vertical position, whereas radiotron No. 13246, type UV-204, may be operated in either a vertical or horizontal position. If mounted horizontally, the plates should lie in a vertical plane, with the seal-off tip down.

FANS, AMATEURS, DEALERS, BROADCASTERS, MANUFACTURERS,
AND THE GENERAL PUBLIC

Are Looking Forward to

NATIONAL RADIO WEEK
DECEMBER 23 TO 30, INCLUSIVE

NEW YORK

Radio Supplanting Land Lines in Northwest

By *Washington R. Service*

RADIO is slowly supplanting government wire lines in the far reaches of the Yukon. Much of the romance of the Far Northwest is passing with the reeling up of miles of wire stretched by men of the Signal Corps, and kept in operation, despite severe winter storms and intense cold, since long before the days of the gold rush.

The first radio station erected in any United States possession to handle commercial business was built in 1903 at St. Michaels, Alaska. Radio then reached to Nome, replacing many

cables and wires. Winter ice across Norton Sound was constantly carrying the hundred-mile cable away and its replacement was expensive, so the stations at St. Michaels and Nome were erected and are still in operation. Later on more stations were erected, chiefly in the interior, until fifteen spark stations were completed.

Arcs and Tubes Replace Spark Sets

During the past summer, all these stations were modernized by a Signal Corps field detachment under command of Captain C. H. Burkhead, who will remain at Fairbanks all winter to

carry on observations as to the efficiency of the newly installed radio equipment. All spark sets were replaced with arc sets, at important points and with tube transmitters at the smaller stations. To-day there is not an army "spark" in Alaska. The modern equipment, it is estimated, will save about 75 per cent of the old operation costs and improve the transmission materially.

Signal Corps radio operators are now working direct from Fairbanks to Nome, a distance of about 540 miles, by radio. The resultant improvement in radio communications has made possible the abandonment of about 200 miles of land wires which had been a tremendous effort and expense to keep in condition, requiring the services of a small army of Signal Corps men, especially in winter time. To-day the army uses a wire from Fairbanks to its cable station at Valdez, but the line from Fairbanks to Fort Egbert was abandoned and the wires west of Hot Springs and Nulato taken down, as well as many lines to the mining centers.

A 300-Mile Radio Control

To-day an operator at Valdez sends communications over 300 miles of wire lines to Fairbanks and thence by radio to Nome, about 540 miles. Actually he operates a radio arc at Fairbanks from his station 300 miles away, which is very "remote control."

In the event of a break in the Signal Corps cable which connects Alaska with the United States proper, the naval radio station at Cordova handles traffic to North Astoria, Oregon, completing the chain to the United States for the army.

Puzzling Problem of Tuning

By *Harold Day*

Schematic diagram of a simple circuit showing the tuning inductance and variable condenser.

TUNING is a puzzling matter for beginners. It is, however, very simple. It is stated that by varying the size of the coil B, and the condenser, the frequency of exchange of electrical energy between them—and, hence, the wave length—may be regulated. Study the circuit shown on this page.

Assume that the wires, KK, are connected to a source of electrical energy, the frequency of which is varied by changing B and C. Vary C, leaving B fixed until a frequency of 1,000,000 cycles, or a wave length of 300 meters, is obtained. Then vary C and D, and it will be found that up to a certain point—and to that point only, the ammeter measuring the current gives a reading. This process is known as tuning and the point at which the ammeter gives reading is known as the

"resonant" point. All transmitting and receiving sets operate in the above manner. The difference in the sets being due to the methods used in varying B and C, and C and D.

Tuning applies to transmitting sets; the action being reversed; and then B and C are varied. High-frequency alternating current will be obtained from the wires KK, but the voltage and current will be in the order of millionths of a volt or ampere. A meter cannot be used. A special device, the detector, is employed, which, with telephone receivers, makes the currents audible.

Keep for Reference When Your Set Fails

IT should be noted that the scheme of connection in a receiving set is almost similar to that of a transmitting set with one exception: a detector and telephones have been added. The operation has already been explained in special articles published in RADIO WORLD. The various wave lengths are obtained by varying the frequency of

Schematic diagram showing complete crystal receiver. D and B are combined in loose coupler. This is so constructed as to permit of variations of D and B.

the circuits and the alternating current obtained from the distant transmitting station which is impressed on the detector.

The coils, D and B, are conveniently combined in the loose coupler. This instrument is so constructed as to permit of ready variation of D and B, and it also permits of the variation of the position of one coil with reference to the other. In the accompanying sketch a condenser, such as C or C₁, is shown.

These simple facts should be thoroughly understood by every amateur and fan. Keep this article and the accompanying diagram for reference.

Cells May Be Varied by Changes in Connections

By Horace Beers

Figure 1. Method employed when connecting up dry cells in series. Drawn by Horace Beers.

A KNOWLEDGE of the methods of connecting up dry and storage batteries may prove useful where other sources of current are not available. Standard-size dry cells are used quite extensively for lighting vacuum tubes by amateurs who are not able or willing to hand out the sum of money necessary for a storage battery. The dry cell may be a fairly good substitute for the storage battery, but its use is not advised, except in emergencies, because these cells soon become exhausted and must be replaced by a new set of batteries. The cost of this continual replacement soon mounts up.

For the vacuum-tube B battery a number of flashlight batteries may be used as the plate potential for the vacuum tubes. Different uses of electricity require different values of voltage and amperage. An audio tube generally takes, approximately, one ampere of current to light at a pressure of six volts. The plate circuit requires a current that is measured in milliamperes, but at a pressure of twenty or more volts.

It must be remembered that a dry

cell has a voltage of $1\frac{1}{2}$ volts when new, and should show about 25 to 30 amperes. The storage cell, after being in use for a short time, registers about 2 volts, but their short-circuit ampere reading should never be considered, as it is ruinous to the cell in making the test. Such cells are rated in "ampere hours." This term may be taken literally, as an ampere hour means the flow of one ampere for a period of one hour. Usually about 8 amperes can be drawn, as a maximum amount, from a 60 ampere-hour storage battery.

For different uses cells may be connected in series, or parallel, or in combination of the two. When we connect in series we increase the voltage. When we connect in parallel we increase the amperage.

Suppose we have 4 dry cells and wish to operate some pieces of apparatus that require 6 volts without a large consumption of current. By connecting the cells in series the total voltage is the sum of the voltages of the individual cells. In this case the cells are $1\frac{1}{2}$ volts each; so 4 in series would give us 6 volts. By series we mean that the center post of one cell is connected to the side post of the other.

If a greater amount of current is needed we can connect our cells in what is known as series-parallel, as

Figure 2. Method employed when connecting up two banks of dry cells in series parallel. Drawn by Horace Beers.

shown in Figure 2. This consists of connecting 2 series sets of four in parallel; that is, by connecting the 2 positives and, likewise, the 2 negative end-poles of the 2 series. Take the leads off as shown. This connection doubles the amperage, while the voltage remains the same. Further increase in amperage may be obtained by adding more banks of cells to the system.

This same rule applies to the storage battery; but, as the batteries register only 2 volts each—three when connected in series—it would give the necessary 6 volts.

These simple facts regarding batteries should be remembered by every radioist dabbling with batteries. A storage battery having 3 cells would register 6 volts; one with 2 cells, 4 volts, and so on. Never connect or short circuit a cell. By this we mean, never place a wire or other piece of metal across the negative or positive of a cell. It will completely ruin it and you will be wondering why the battery will not produce current.

Erecting Aerial Masts

A SIMPLE way of raising aerial masts to any considerable height is to plant a short staff about one-third the length of the main mast, close to its base and raise the shorter mast by means of tackle. Guy ropes should be slung from the mast about two-thirds the way up, to permit guiding.

It is usual to make the aerial of more than two spans of wire, so that a greater conducting surface will be represented. For stations up to 1 kilowatt, size and aerials should have at least 6 wires spaced not less than 2 feet apart or more than 3 feet.

It has been found that nothing is gained by placing the separate spans closer than 2 feet. For fairly large aerials, 3 feet is very good spacing.

A RADIO BUG'S IDEA OF PARADISE

Radio Angel: "Help yourself, son. If you don't find all you want this trip, come again!"

Radiograms

Latest Important News of Radio Garnered from the World Over, and Reduced to Short Wave-Lengths for the Busy Reader.

RADIO is playing an important part in the work of mapping Northwest Canada. By tuning in and getting time signals from a known distant point and comparing it with the time at a designated place the map-makers can easily ascertain distances and directions.

* * *

Scientists have discovered that the aurora has a decided effect upon radio. Apparatus affected by the aurora could receive, but not transmit, signals while the influence lasted.

* * *

SAM is the call of a new radio-compass station at Hallo on The Skagerrak, Sweden, which was opened for general service on November 1. The new station, which is operated through Goteborg, SAB, will determine the true bearing of vessels calling within 150 miles on a 600-meter wave length. The charge for a bearing is placed at five kronor, about \$1.34.

* * *

The Radio Corporation of America has announced a radio-letter service to London and Germany at a rate slightly higher than postage. The rate is six cents per word. Messages filed any day in the week up to Saturday marked "Radio-letter" are transmitted to London or Germany for delivery on the following Monday morning.

* * *

The United States Signal Corps at Washington, D. C., continues to save money through the transmission of official messages by radio instead of by land wires. In September a total of 239,826 words were handled, with a saving for the month of \$2,668 over the cost at commercial rates.

* * *

Radio wins a race! "Radio," ridden by L. McDermott, won the Latonia Cup at Louisville, Kentucky, with an added purse of \$7,500, over a distance of two miles and a quarter in 3:49 flat.

* * *

Recent modifications of the rigid laws governing the installation of radiotelephone and telegraph stations have made possible the installation of radio-broadcasting, according to Vice-Consul Edwin B. Montgomery, of Montevideo. Applications are now pending which, if granted, should mean the opening of a splendid market for radiotelephone receiving apparatus in Uruguay.

* * *

Fred Stone, president of the National Vaudeville Artists, was the guest of honor at a luncheon at the William Penn Hotel, Pittsburgh, given by prominent citizens. All the speeches made were sent out by radio. Among the speakers were: Harry Davis, Senator John P. Harris, president of the Theatre Managers' Association of Pittsburgh; Senator George Wharton Pepper, Senator David Aiken Reed and Mayor W. A. Magee.

* * *

Gambia, the British colony in West Africa, has installed radio telephone and telegraph stations at Bathurst and McCarthy Island, 176 miles apart. The new stations are in daily use, giving instantaneous communication between the two centers. The colony has no organized wire telegraph or telephone system, and the radio stations already have proven of great value.

* * *

Members of the United States Army, organized reserves and National Guard in San Francisco will have the opportunity to buy some of the 10,000 army receiving sets at \$7.50 each. These sets were declared surplus stock, and cost \$1,000,000. Buyers are limited to military men only.

* * *

The call letters for the station recently opened at Havana, Cuba, are PWX.

* * *

Great Britain has given the Wireless Society of Manchester permission to erect a special transmitting station for the purpose of attempting to bridge the Atlantic from the east to the west with one kilowatt of power. The extraordinary license issued for this station specifies that no more than this amount of power shall be used and that the apparatus shall utilize continuous waves. In Great Britain the restrictions which have always been maintained on amateur stations even specified what kind of aerial should be used, and placed limitations upon its size. In the license given to the Manchester society this rigid rule has also been modified, and permission granted for the erection of a more efficient type of aerial for the purpose in view.

* * *

The steamer "Matsonia," equipped with a 1,000-watt General Electric Company radio set, talked through its telephone every morning from September 12 until September 25, the day before she arrived in San Francisco from Honolulu, with the radio station

at Apia, Samoa. The last conversation was at 8:30 o'clock in the morning. At that time the "Matsonia" was 4,050 miles from Apia. On this voyage the "Matsonia" was in radiophone communication the entire trip with either the San Francisco office of the Radio Corporation of America, KTH, or the Hawaiian station, KHK. All the ship's radio work was done on a wave length of 550 meters.

* * *

Experiments are being made in Belgium for rapid reception of messages in script by a photographic process combined with radio.

* * *

Radio development in Czechoslovakia has not yet passed the stage of infancy, according to dispatches to the Department of Commence from Consul Winans, Prague. He states, however, that the government has already taken an active interest in radio development, and in view of a more extensive and popular acceptance of this form of communication at home has sent a special commission of experts to study the progress made in other countries. Whether a sending station for radio messages will be established in Czechoslovakia will depend upon the findings of this commission. Even when finally introduced, however, the local industry cannot be expected to attain the state of development reached in the United States. It is stated by the Ministry of Posts and Telegraphs that all messages sent by radio will be subject to strict control by the Government; not every person will be permitted to own a receiving or sending apparatus. High duty will be assessed on radio outfits and supplies of foreign make, and each radio set, whether of domestic or foreign manufacture, will have to be registered at the Ministry of Posts and Telegraphs. Many local factories are said to be interested in the future of radio telephony and to be awaiting a favorable moment for producing the necessary requirements of the industry.

* * *

Over 5,000 words on the election results in New York and other parts of the East were sent to California by radio on election night, the wire service having been seriously interrupted by a sleet storm in the Rocky Mountains. The station of the Radio Corporation of America at Rocky Point, which is ordinarily used for sending radio messages to Europe, sent returns to the radio station at Bolinas, near San Francisco, which is ordinarily used only for communication with the Far East. Western returns also were received by radio from Bolinas.

* * *

Beginning November 26, the radio audiences will hear the first of a series of thirteen Sunday afternoon popular concerts by the City Symphony Orchestra, which will be broadcast by the Westinghouse-Radio Corporation station, WJZ, at Newark. These concerts will be held at the Manhattan Opera House, New York City, and will be conveyed to WJZ by a special Western Union wire. The programs will consist of gems from the lighter classics, together with shorter symphonic poems. Young soloists of real talent and distinction will be heard at each performance. The City Symphony Orchestra, which is maintained by the Musical Society of the City of New York, consists of 83 players carefully selected for their musical talent and symphonic experience. The conductor, Mr. Dirk Foch, a native of Holland and a composer of distinction, has had a successful career as a conductor of symphony concerts and opera in Amsterdam, The Hague, Stockholm, Gothenburg, and other European cities.

* * *

"Aida," Verdi's great opera, was broadcast from the Kingsbridge Armory, New York City, on Saturday evening, November 11. The performance—which marked a new era in radio and made history for this wonderful science—was given by artists and the orchestra of the Metropolitan Opera House, New York City, undoubtedly the greatest organization of its kind in the world. Sent out by the powerful station, WEA, it was heard over a range of a thousand miles.

Send Radio World Your
Best Suggestions for
National Radio Week

Radio and the Woman

By
Crystal D. Tector

AMONG the many letters that I have received since the movement for National Radio Week started but one contains a negative note. Now, I wouldn't mention it—at least, first of all the communications that have come to me—if I did not believe that every objection contains some possible suggestion for good. I once belonged to a club, and one of the members seemed to take particular pains objecting to everything—everything! She called herself the "natural born objector." We other women almost hated to start anything new, knowing that this particular member would never agree. We have all encountered such a person. But they seldom do as much harm as good—and it is generally good business to have one on a committee.

* * *

Well, the correspondent I started out to write about is a Miss Jane Drophie of Chicago. Her objection is summed up in one sentence which I cull from her letter: "Won't the men take all the glory of National Week and won't they get on all the committees and have everything their own way?"

* * *

I imagine that Miss Drophie hasn't advanced much in up-to-date matters pertaining to women's place in the world—even if she does live in Chicago. My reply to her, and to any other woman who feels that we women are going to take a back seat during National Radio Week, is this: 'If such a thing comes to pass, it will be the fault of the women and the women only! And I think that I am sufficiently acquainted with my sex to make the statement that we will have just as much to say as the men—and, whisper, perhaps a little more!

* * *

Let me tell you a few of the preparations that the radio women of the charming suburban town—just a pleasant ride from New York—where Friend Husband and I have the dearest little home in all the world, are making for National Radio Week.

* * *

First we organized the Women's National Radio Week Executive Committee. We could have had fifty members, but at the first general meeting we all decided that a small workable committee with absolute powers would be the most satisfactory. So a committee of nine was decided on. The chairman of our first meeting appointed four, and the remaining five were chosen by ballot—that is, everyone at the meeting was asked to cast a ballot for her choice and the five polling the highest votes were declared elected.

* * *

This committee has the power to appoint subsidiary committees on publicity, dealers, shop-window decorations, entertainment, and any other phase of radio that may seem necessary. We consider that one of our most important committees is the Committee on Church Program and Entertainment, for no little interest in radio is centered in the churches in my town; and, this winter, we look to some wonderful evenings, as not a few of the churches have splendid sets. However, this particular committee will endeavor to have special radio nights and afternoons in as many churches as possible during National Radio Week—jolly entertainments and socials where people will meet and get acquainted, and, we all hope, become radio fans.

* * *

Another committee of importance will work among what we call "radio strangers." The members of this committee will visit those who have taken no interest in radio, and try to bring them to the church entertainments, the affairs at different homes, the radio stores where the general broadcasting may be heard, and to advise the most practical reading in order to learn radio. You may imagine that such a committee has a good deal to do; but from the reports I have received, our committee is doing wonders. I can safely say that, during the past ten days, we have made radio converts at the rate of a dozen a day. I do not mean people who promise to take an interest and then bid you a cheerless farewell; but people who have become so interested that they have not only thanked you but have asked you to come again.

* * *

We also find that one of our busiest committees is going to be the one that will advise shopmen how to decorate their windows and make their stores attractive. As we all know, the average radio dealer, or electrical merchant, is a pretty busy man in the first place, and, in the second, his wares do not make very attractive window and inside displays. Now here is where we women can do yoemen's service. I am certain

that as National Radio Week approaches few radio dealers will object if one or more polite, well-intentioned women approach them and ask if they may show Mr. Dealer or Mr. Shopkeeper how to present his goods in a way that will not only make them decorative but attractive to the prospective buyer.

* * *

Then, too, we women can do much to give the many social affairs that are bound to make National Radio Week sparkle the very *eclat* they will need. We will be of great service in getting up programs for the younger set—meetings and dances with radio as the foundation and the background. Why, already, I have had over a score of hidden requests for invitations to several affairs that I have announced—and I only wish that my home were larger—as large, indeed, as a barn or as the Pennsylvania railroad station in New York City—and I would just issue, right here, in the columns of *RADIO WORLD*, a general invitation to all to be present. "The more the merrier," say I.

* * *

I think that I have given my women readers a few hints here. One clever hustling woman in any town can easily start this movement going. It will be surprising how quickly it will take hold. For radio is new, and we Americans are ever on the alert for something new. It won't be long before the spirit of the thing will spread, and, I am bold enough to make the assertion, in any red-blooded American town, doing something for National Radio Week, or being on a National Radio Week committee, will be very much the vogue.

* * *

And, let me tell you in advance, there is to be some wonderful broadcasting this winter. We are to hear grand opera by the artists and the orchestras of the Metropolitan Opera House, New York, the very finest thing of its kind in all the world. We are to have the rendition of symphony orchestras that comprise the highest-paid musicians. We are to have the news of every great event. We are to hear eminent singers and instrumentalists—and we will have plays produced that, otherwise, we might never have a chance to see or hear. So, you see, radio is working for a wonderful future, and National Radio Week promises, more than anything else, to give us a glimpse of that future.

* * *

I can't help being so enthusiastic because I so fully believe in it. And I want to help you—all of you women who are interested in radio! And the editors of *RADIO WORLD* will help me to help you by devoting these columns to you every week.

Boys! This Tells You How to Use an Antenna with Your Kite

There are times when boys like to experiment with something more than the plain aerial. In the accompanying photograph, two of the younger radio enthusiasts are seen on the roof of their home in an attempt to raise a kite. It is their intention to utilize this kite by attaching a wire to it in order to experiment with altitudes higher than those of the average roof aerial. Their receiver is of the crystal type, and when the kite is aloft some thousand feet, unusual results may be obtained. This is an experiment to find out whether the height of an aerial has any more or less effect on the volume or distance of signals. Instead of flying the kite with a string, a light wire is used.

(C. Kadel & Herbert)

Another Busy Radio Week

(C. International News Reel)

(Above) Every man his own aerial! This is a possibility, according to Collins Penz, a radio fan of Minneapolis, Minnesota. Mr. Penz has a small set in his home. One day, during a testing out while it was hooked up, he noticed that he could hear a broadcast concert while he kept his fingers on the slider of the tuning coil, as shown in the photograph; but when he removed his fingers, the music was not audible. His body served as a natural aerial. Mr. Penz made his coil by winding two coils of wire—one large and one small—around an ordinary megaphone. This gave him a primary and a secondary winding, making it a loose-coupler.

(Below) The pensive man in this photograph is Alfredo Zayas, President of the Republic of Cuba, in his private office just after talking into a microphone. It was the occasion of the broadcasting of the Cuban president's address to the American people, which proved that the span between the two republics may be covered by radio in the fraction of a second. Radio development in Cuba is having a great boom—particularly since the broadcasting of the World's Series baseball game was received there so clearly. Several new high-power stations are to be erected in Havana. General interest in radio matters is thoroughly active and amateurs are becoming more numerous every week. Cuba is a hearty market for American radio goods.

Here is Miss Stevens decoding a "radio-photo" of Miss Virginia Valli, Universal Film star, which was sent from London to New York by radio. On the artist's drawing board are two portraits of Miss Virginia Valli. The picture on the left of the board is a copy of the portrait transmitted through the air; on the right is the result of Miss Stevens's decoding. She is now engaged in perfecting a method of transmitting finger-prints by radio, in the United States. To the left is a facsimile of a coded portrait as received by Carl Laemmle, president of the Universal Film Manufacturing Company. Sending photographs by radio is becoming a simple matter. It is possible to radio photographs over a great distance, one having been successfully sent from Italy to the United States.

(C. Wide World Photos)

(Above) This picture shows a remarkable radio set made by boys. To be sure, they had the guidance of a capable instructor. This particular set is for long-distance reception. Radio World would be pleased to see photographs of sets made or assembled by other boys, and invites them to send in such pictures with a view of having them published for the benefit of other boys.

(C. Kadel & Herbert)

(Above) The football season has been considerably augmented by radio. Broadcasting the big games is very much in vogue. As in the case of the World's Series, these most interesting athletic events, so important to lovers of American sports, were received, play by play, in thousands of homes all over the country. The photograph illustrates the receiving and sending station at Fordham University, New York, designed primarily for the exchange of football scores and relay work between the various colleges. This station operates on 200 watts and uses from two to four U-V 203 tubes. Edward J. Hefele, one of the students of Fordham, is shown in the photograph broadcasting a football game taking place on the college grounds.

(C. Kadel & Herbert)

(Above) Mr. Shou S. Man, a graduate of the Hong Kong University, testing out the static characteristics of vacuum tubes at Columbia University, New York. Not a few young Chinese have come to the United States to learn the mysteries of radio. Few users of radio realize how much work is involved in the manufacture of vacuum tubes.

(C. Central News Photo Service)

(Above) Arthur Alexander, the American tenor, announces that his avocation is radio. This successful young singer is one of the most ardent fans in the country and says that he wouldn't care if he were a radio operator aboard an ocean liner.

(Left) The motorcycle is the latest thing to be radioized. And it works! Neil Cochran, of Oakland, California, is shown here tuning in on the radio station of "The Tribune" of that city. Mr. Cochran drove the radio-equipped motorcar which trapped the "bandit" in the recent "bandit chase" held in his State.

Radio-Wire Tables

By Frederick J. Rumford, E.E., R.E.

No. 1—Enameled Magnet Wire

Showing the Number of Feet of Magnet Wire in a Pound and Fractions of a Pound

APPENDED is the first of a series of five tables which the radio amateur will find useful for many purposes. The succeeding tables—"Single Cotton-Covered Wire," "Double Cotton-Covered Wire," "Single Silk-Covered Wire" and "Double Silk-Covered Wire"—will be published in early numbers of RADIO WORLD.

No.	Diameter in mils.	Approximate turns per square inch	$\frac{1}{8}$ lb.	$\frac{1}{4}$ lb.	$\frac{1}{2}$ lb.	$\frac{3}{4}$ lb.	1 lb.
20	.0337	885	40	80	160	320	320
21	.0302	1,126	43	86	172	258	404
22	.0269	1,400	63	126	252	378	509
23	.0241	1,736	80	160	320	480	642
24	.0215	2,160	101	202	404	606	810
25	.0192	2,770	127	254	508	762	1,019
26	.0171	3,460	160	320	640	960	1,286
27	.0153	4,270	201	402	804	1,206	1,620
28	.0136	5,400	255	510	1,020	1,530	2,042
29	.0122	7,900	321	642	1,284	1,926	2,570
30	.0109	10,000	405	810	1,620	2,430	3,240
31	.0097	12,620	510	1,020	2,040	3,060	4,082
32	.0087	16,020	641	1,282	2,564	3,846	5,132
33	.0077	20,400	805	1,610	3,220	4,830	6,445
34	.0069	25,200	1,010	2,020	4,040	6,060	8,093
35	.0062	31,900	1,274	2,548	5,096	7,644	10,197
36	.0055	40,000	1,601	3,202	6,404	9,606	12,813
37	.0049	51,600	2,013	4,026	8,052	12,078	16,110
38	.0044	65,700	2,534	5,068	10,136	15,204	20,274
39	.0039	81,600	3,189	6,378	12,756	19,114	25,519
40	.0035	14,000	4,013	8,026	16,052	24,078	32,107

The figures for the $\frac{1}{8}$ -, $\frac{1}{4}$ -, $\frac{1}{2}$ - and $\frac{3}{4}$ -pound wires are a few fractions off, but not sufficient to cause any harm. The computations were made in this way in order to eliminate decimals.

Uncle Sam Turns Out Two New Amplifiers

One Is an Electron-Tube Amplifier Using 60-Cycle Alternating Current to Supply Power for Filaments and Plates. The Other a Radio-Frequency Device Using the Transformer Coupling Method

AN amplifier which has the advantages of low first-cost and cheapness of operation, besides doing away with the inconvenience of the storage battery and the B battery, was developed recently at the Bureau of Standards, Washington, D. C.

A crystal detector and 5 stages of amplification, 3 stages of radio-frequency amplification and 2 stages of audio-frequency amplification are used. The first arrangement tried consisted of 1 radio-frequency stage of amplification, tube detector, and 1 stage of audio-frequency amplification. The filaments of the 3 tubes were lighted by 6 volts supplied by a stepdown transformer, the primary of which was connected to 110-volt, 60-cycle power mains.

It has been found that either air-core, or iron-core, transformers may be used for coupling the output of one tube to the input of the next tube. The air-core transformer gives more amplification per stage, but is responsive to only a narrow band of frequencies owing to the low effective resistance of the windings. The iron-core type, while not giving as much per stage, allows amplification over a much broader band of frequencies.

A special type of air-core transformer which will respond to signals on wave lengths from 600 to 1,000 meters has also been developed. The coils of the transformer were wound in the form of a flat doughnut, the wire being wound in a manner similar to that of the open, or basket, type of coil winding. They are wound continuously from the inside to the outside. Two of the coils constitute an air-core transformer, one coil being connected in the plate circuit of one tube and the other being connected to the grid circuit of the succeeding tube. It is found that when the primary and secondary transformers are placed about $\frac{1}{2}$ inch apart the transformer gives best amplification at 600 meters, and when the coils are placed close together the amplifier operates best at 1,000 meters. This is due to the increase of the capacity between the coils when placed adjacent. An amplifier has three stages of radio-frequency, two stages of audio-frequency amplification, and a detector tube.

Scientific Paper No. 449 of the Bureau of Standards, Department of Commerce, describes the construction of a new radio-frequency amplifier which uses the trans-

former coupling method. Radio-frequency amplification consists in the amplification of the received radio-frequency current before it is detected. By the use of radio-frequency amplification and a coil antenna a signal which is very feeble can be made loud enough to be heard throughout a large room.

Three methods are described by which the electron tubes may be coupled together so as to give radio-frequency amplification—resistance coupling, tuned-plate coupling, and transformer coupling—the latter having been found most satisfactory.

In order to operate well the radio-frequency amplifier should have a transformer designed so that it will have small capacities in the windings as well as between the windings, and in connecting the transformer in the amplifier circuit care must be taken to have all connecting leads as short as possible.

The alternating current was rectified by means of a gas-filled, two-element rectifier tube, called a "Tungar" tube; but it was found that the residual hum was greater than when the alternating current was not rectified.

When an electron tube is used as a detector there is impressed on both the plate and filament a 60-cycle alternating current voltage, which, although small, becomes objectionable when amplified by one or two stages of audio-frequency amplification. When, however, a crystal detector is used instead of an electron tube detector it has been found that the 60-cycle hum is practically eliminated and that the crystal gives as good rectification as the tube detector.

After much experimental work a circuit consisting of three stages of radio-frequency amplification, galena crystal detector, two stages of audio-frequency amplification, loud-speaking reproducer, and the necessary power transformer and rectification circuits were found which allowed the reception of music and telegraphic signals without too much interference from the humming noise just mentioned.

Mr. Miller's Circuit from Another Angle

EDITOR, RADIO WORLD: In reference to your request for information relative to the new circuit for experimentors in RADIO WORLD, No. 30, dated October 21, the writer notes that Mr. W. Miller, Southern Methodist University, Dallas, Texas, claims to have worked out this circuit. Possibly he did. However, the writer, also Mr. J. Fisher, of this city, have been using this circuit for about one year, not as Mr. Miller describes it, however, which in the writer's estimation, is a very cloudy method. In the place of the D-L 50-coil, a variometer should be used. This gives tuning over the entire wave length unless one is looking for Japanese or Chinese stations on the Atlantic Coast. In addition to this, a .00025 mfd., should be discarded for a variable condenser. Then by using one stage of audio frequency in connection with this circuit, one is able to tune in sharply and receive stations anywhere from 600 to 1,000 miles.—F. D. Tyndall, 836 Kingston avenue, Oakland, California.

Help to Squelch QRM

Suggestion that "The Rochester Plan" Be Put in General Force to Prevent Conflict Between the Novice Listener and the Radio Amateur

AS a result of experience through the past year of broadcasting, we have a definite program to recommend for amateur consideration. There have been many unjustified complaints against amateur QRM; and, of course, where amateurs in cities have hogged the air all evening there have been justifiable complaints. Most of us have realized, says Kenneth B. Warner, editor of "QST," November, that broadcasting was capable of becoming a powerful force for good in our country, of tremendous social, economic and educational value, and have known that meant the passing of the old days when we could pound brass from supper-time on and the ushering in of a new era when the air had to be shared. As we have pointed out previously, many of us have gone so far in the business of sharing that we have almost been afraid to operate at any time, and amateur radio has suffered for the lack of a definite plan. On the other hand there are uniformed novice listeners who object to amateur transmission at any hour of night, and again the need for a recognized scheme has been shown. This we now offer.

Broadcasting is admittedly an institution of the early evening hours. That is the time that quiet air should prevail, when the greatest good can be done for the greatest number. When should we open up our stations for transmission? Our board has considered that question and has decided upon 10.30 p. m. as the proper time. We're regretfully obliged to conclude, fellows, that the time is here when we should voluntarily keep our transmitters silent during the early evening hours if their operation interferes with listening. This means that in all congested communities amateur stations should be quiet between the hours of 7 p. m. and 10.30 p. m. This is no new thing for most of us—we've been doing it already—but it makes it a recognized principle of amateur work.

We urge our members and clubs to get together with the listening-in element in their community and have an understanding on the subject. Acceptance of this plan on the part of the amateurs means that they recognize the rights of the listeners to hear their concerts undisturbed, and that they will keep quiet between these hours. Acceptance of this plan by the novice listeners means that they recognize the rights of us amateurs to transmit and carry on our useful work and that they will not complain against the "meaningless buzzes" when the lid goes off at 10.30. This plan was proposed at a meeting of all radio people in Rochester, recently, and was adopted as a solution of the local difficulty. We may well call it "the Rochester Plan."

Whenever a community gets together and agrees upon such a plan, we feel that it should become as law and that the mere possession of a transmitting license should not entitle an amateur to go contrary to the sentiment of all his fellows. It is our view that such operation, unless justified by an emergency or official tests, would constitute deliberate and malicious interference within the meaning of the federal radio law, and we believe the Department of Commerce will agree with us. On the other hand, in localities where this plan is adopted and quiet air is maintained between 7 and 10.30 p. m., we will expect amateur transmission to proceed without complaint after 10.30, and the A.R.R.L. will protect with every

resource at its command the right of any of its members to so transmit if unjustly accused while legally operating in such a community.

Now we have a working plan. Let us adopt it, fellow amateurs. This puts an important duty of self-policing on the shoulders of our affiliated clubs and we are depending upon them to handle the job. When this plan is adopted it must be respected, religiously, and this means that unlicensed and improperly adjusted stations must be hunted down and turned in. In bygone days such a station bothered no one but its neighborhood amateurs, and if they could put up with it there was no harm done; but today such a station will bring discredit upon all of amateur radio and must not be permitted to exist. We would suggest that clubs establish committees to help local amateurs and render assistance when needed to get a station properly adjusted, but if the operator persists in operating illegally after being warned he should be turned in to the inspector without mercy—we have too much at stake. Other folks are watching us too; and while we think about it, we want to tip off everybody to get their station and operator licenses renewed promptly upon expiration.

What about local work, which used to occur in the early hours of the evening? Honestly, we don't know, and it will be up to the amateurs of each club to decide for themselves how they will divide their hours. The time after 10.30 is going to be very precious and, solely because it is not as important as DX work, we are afraid local work will have to be got over with by the time 7 o'clock rolls around. Low-powered battery-operated CW sets of course can be used for local work all evening long and not cause a particle of QRM for the broadcasting fan next door, but most of the lads who do local work have a far different kind of equipment!

Our transmitters must improve. There will be too many of us with traffic to move at 10.30 and too many listeners with dumb-bell tuners for us to continue much longer with the cycle-consuming spark of pre-war days. For the very efficiency of our traffic moving the selfish spark will have to yield to the valve set. We hasten to say, though, that there are selfish CW sets too, and we are just as much agin a bum CW without rectifiers and filters as we are against the ordinary spark, and for exactly the same reason—it takes up too big a place in the air, its wave is too broad. We cannot be pushed into an adoption of CW versus spark against our will, but left to our own devices we believe it is evident to any thinking amateur that the quiet efficiency of the little bottles is just the thing we need—filtered DC, CW transmitters.

Now let's get busy on our self-imposed 10.30 lid. Remember that the League does not feel that it can back a member who runs loco in a congested locality and smears a whole county with QRM from the minute his supper is down, but that it will safe-guard the interests of its law-abiding members in communities where the Rochester Plan is adopted and respected.

One thing more. Noise this about a bit. Let it be known that we amateurs have decided among ourselves to preserve some quiet hours, out of consideration for the broadcast listeners. Spread a little honest propaganda in your local newspapers.

THE Magnavox Company have been pioneers in the development of devices for sound amplification. When you purchase a Magnavox Radio or Magnavox Power Amplifier you possess an instrument of the very highest quality and efficiency.

Type R-2
Magnavox Radio
with 18-inch Horn

THIS instrument is intended for those who wish the utmost in amplifying power; for large audiences, dance halls, &c., but requires only .6 of an ampere for the field.
Price, \$85.00

Type R-3
Magnavox Radio
with 14-inch Horn

THE same in principle and construction throughout as Type R-2, and is ideal for use in homes, offices, amateur stations, etc.
Price, \$45.00

3-Stage
Magnavox
Power Amplifier
Model C

INSURES getting the largest possible power input for the Magnavox Radio. Can be used with any "B" battery voltage which the power tube may require for best amplification.

AC-2-C, 2-Stage..... \$80.00
AC-3-C, 3-Stage..... 110.00

Magnavox products may be had of good dealers everywhere.

Dr. Alfred N. Goldsmith Invents Device to Improve Tone Transmission

No. 1,432,456. Patented, October 17, 1922. Patentee: Alfred Norton Goldsmith, New York, N. Y.

DR. ALFRED N. GOLDSMITH, secretary of the Institute of Radio Engineers and chief of radio activities at the College of the City of New York, has been granted letters patent on an apparatus to improve the tone transmission from a sustained wave-generator.

Since sustained wave-transmitters produce signals consisting of constant-amplitude radio-frequency current, such signals are inaudible, or practically so in a receiving system having the usual rectifying detector, such as a crystal or vacuum tube. Notwithstanding this fact, transmitters on ship board which may be called upon for distress signals, are compelled by law to be capable of radiating a signal wave of such character that it is possible of reception and detection in a simple detector of a receiving set.

It is accordingly highly desirable, and even necessary, to provide a method of controlling and modifying the sustained wave-radiation of an arc, alternator, oscillating vacuum tube, or other sustained wave-transmitter so

Figure 1 is a diagrammatic representation of circuits and apparatus for carrying out the invention of Dr. Alfred N. Goldsmith. Figure 2 is a detail side view of the rotator of the modulator.

that periodically modulated radiation is capable of being produced; that is, the amplitude of the radiation should be periodically varied at audio-frequency.

This method of modulation may be advantageously applied to apparatus for transmitting from a sustained wave generator, in the belief of Dr. Goldsmith.

on a map, or chart carried by a moving body, the movements of that body and give its location at any time.

This is one of the most important radio inventions of the day.

Spark-Gap Improvement
No. 1,428,856. Patented, September 12, 1922. Patentee: Leslie O. Parker, Swissvillia, Pennsylvania.

MY invention," says Mr. Parker in his patent papers, "relates to wireless apparatus and, particularly, to that class of apparatus which employs two relatively movable electrodes, one of which is stationary and the other a rotatable toothed disk, the teeth of the latter moving past the tip of the stationary electrode to make and break a circuit across a gap located between.

"In order that the make and break shall occur at the peak of the voltage

Figure 1 is a longitudinal sectional view of a high-frequency wireless generator equipped with a spark-gap structure embodying this invention, and Figure 2 is detailed view of parts of the generator and the mounting for the stationary electrode.

wave, it is necessary that the electrodes shall be relatively adjustable to permit them to be correctly positioned with relation to each other. This adjustment is usually effected by moving the normally stationary electrode circumferentially of the rotatable electrode.

"My invention is to provide a spark-gap structure in which the normally stationary electrode shall be supported by, and insulated from, the end bracket of an alternator in a simple and inexpensive manner, and so arranged that it is readily adjustable on its support and accessible for inspection and repairs.

East Harlem Radio Club Elects Officers

THE Radio Club of East Harlem, New York City, organized September 20, 1922, has elected the following officers: Harold Itzel, president; John N. Itzel, secretary, and John D. McEvily, treasurer. The club meets every Wednesday at the Federation Settlement, 127 East 106th Street, New York City, at 8 o'clock. Any radio fan who desires to become affiliated with this organization may do so by writing to the Radio Club of East Harlem, Harold Itzel, president, 175 East 111th Street, New York City, for particulars.

Will Locate Moving Bodies by Radio

Wiring diagram showing the arrangements of the circuits of Mr. Connors's invention at two transmitting stations and a control station.

No. 1,433,979. Patented, October 24, 1922. Patentee: Walter W. Connors, Elizabeth, New Jersey

THE invention of Walter W. Connors is an apparatus for determining the actual location and actual movement of bodies. It will find, also, the actual location of a transmitting or a receiving station. The altitude of a receiving station may be ascer-

tained and represented in miniature. The location and movement of anything movable equipped with a receiving station may be indicated.

The distance of a receiving station from a transmitting station, as well as its geographical location, may be ascertained by this invention. It will indicate and trace

Radio to Decrease News Costs

Far East and Pacific Island Tolls Now Too Costly for Commercial Relations

THE scheduled agendum of the Commercial Congress of the Pan-Pacific Union, opened with consideration of "Trans-Pacific Communication," introduced by a comprehensive report by V. S. McClatchy, publisher of the Sacramento "Bee," regarding cable and radio service and suggestions for improvements. Particular attention was paid to news communication as foundation for knowledge and understanding necessary for promotion of peace and enduring commercial relations among the nations of the Pacific.

There are two cables across the Pacific—one from San Francisco to Shanghai via Hawaii, Guam and Manila (Cavite); the other from Vancouver to Hong Kong via Australia, both controlled by British interests. One carries news from Canada to Australia for 5 cents per word; the other, from San Francisco to Manila for 27 cents per word.

The British government encourages news interchange with its dominions by forcing the cable companies to give a low rate for the service; for instance, 7½ pence from London to Melbourne. The United States has sought to secure similar results by using its Navy radio for transmitting news between San Francisco and Manila for 6 cents per word; between San Francisco and Honolulu for 3 cents.

The report declared that radio rather than cable must be looked to for the immediate future for increased transmission facilities on the Pacific.

It was pointed out that a request from China would secure the use of the United States radio station at Pekin for news interchange with the United States through relay at Manila, pending the time when the Federal Telegraph Company of California will have considered its great station at Shanghai for direct communication with California; that Japan can now use her stations in cooperation with the United States Navy station at Honolulu for news intercourse with Uncle Sam without violating her exclusive contract with the Radio Corporation of America as to commercial messages between the two countries; that in this way news rates with China and Japan could be reduced at once from 32 and 27 cents per word, respectively, to a maximum of 9 cents; that Australia can reach Honolulu now by cable to Suva and wireless through Tutuila, and later by wireless direct through her proposed great station; that the Dutch East Indies and French Indo-China have already contracts with the United States navy for radio communication for commercial messages with the United States through Manila, and that the Navy Department will cooperate in establishing a low news rate with these countries.

Reducing Antenna Resistance

IT is the antenna charging-current at the transmitter that produces the signals at the receiver, and in order to get a large antenna current with tube sets, resistance of antenna systems must be reduced to a minimum. In addition to the usual metallic earth plate a counterpoise, consisting of a number of wires spread on the ground underneath the antenna, will materially reduce the total antenna-resistance. The antenna should be constructed and supported so that its electrical period will not vary through swinging. As will be seen, most of the tube circuits shown in this bulletin use the antenna as the capacity element of the oscillating system.

A Chemical Liquid

Manufactured by Krystal-Kleer Co., 2378
Third Avenue, New York City

KRYSTAL-KLEER is a recent chemical discovery used in cleaning crystals when they become covered with oil from handling. It is a combination of chemicals and is very powerful, acting immediately when applied to surface of the crystal. It also makes it sensitive to the slightest touch of the catswhisker. All else needed is an ordinary nail-file. File the surface of the crystal a little, then with a drop of this chemical on a small piece of absorbent cotton, rub the surface thirty seconds.

Manufactured by W. J. Radio & Mfg. Co.,
3020 Fourth Avenue, South Minneapolis, Minn.

A SHORT-WAVE coupler completely connected. Tested out and found to give wonderful results on the broadcast wave-lengths in conjunction with vacuum tubes. All one has to do is mount and connect in circuit. There are no taps to solder; no extra switch at side; no electrical connection to any shaft. Compact and rotor always in center of field. Primary is wound with green silk wire. Of good construction and neat design.

Heard at the Radio Counter

A Conversation Between Customer and Radio Clerk

(Part V)

"CAN you tell me if I may use radio frequency with my set?"

"What type set have you?"

"I have a two-stage regenerative set of the audio-frequency type."

"Not very well. When using radio-frequency, it must be understood that you will have to remodel your whole set. I would advise you to keep the regenerative set you have on hand and start in building a radio-frequency receiver."

"Do you think a radio-frequency receiver is better than an audio-frequency regenerative receiver?"

"For the radiophone broadcast listener, I would suggest building a radio-frequency receiver, for these reasons: In the first place, radio-frequency transformers are made to cover a wave-length range from three hundred to five hundred meters, limiting the power amplification between those wave lengths. Secondly, a loop aerial must be used with this type receiver, due to the high power of amplification which would allow the remarkable advantage of eliminating interference not possible with the outdoor aerial."

"Well, that sounds good. Better get me started on this receiver right away!"

"Very well. Here is your diagram and make-up of the set; also, three radio-frequency amplifying transformers, three tubes, and three sockets."

(To be continued)

Sidbenel Enlarges Plant

THE Sidbenel Radio Equipment Manufacturing Company, Inc., New York and New Jersey, manufacturers of the famous Sidbenel A and B Battery, which proved so successful that they are compelled to increase their production facilities and enlarge their plant in order to catch up with the demand for their batteries and various other products.

This firm has acquired the services of Sidney Isaacson, a prominent battery engineer. He has been appointed general sales manager for Greater New York, with offices at 1663 Jerome Avenue, Bronx, New York City.

What One Advertiser Writes About Radio World Results

CHAS. FRESHMAN COMPANY

Incorporated
97 Beekman Street
New York City

November 7th, 1922.

Radio World,
1493 Broadway, New York, N. Y.

Gentlemen:—We wish to thank you for your successful effort in getting additional advertising copy on our Variable Grid Leak and Micon Condenser in your publication to appear in the issue of Saturday, November 11th, 1922.

The reason that we sent you the copy at such a late date was that it has been our policy to advertise only one of our various products in each magazine, and we had an advertisement running on our Noiseless Tested Micon Condenser for your coming issue.

The results that we obtained from our first advertisement of the Variable Grid Leak and Micon Condenser combined were so great that we did not want to miss the opportunity of having it re-appear in the current issue.

It might interest you to know that outside of the general publicity that our Variable Grid Leak and Micon Condenser combined received from the first advertisement in your publication that we have received hundreds of direct orders from individuals and payments enclosed mentioning the fact that they saw the advertisement in RADIO WORLD. These inquiries came from all sections of the country.

We wish to congratulate you on the exceptional distribution of your publication.

Yours very truly,

CHAS. FRESHMAN COMPANY, INC.

(Signed) Myron Goldsoll

Vice-President in Charge of Sales

"Decrease" in Broadcasting Not Bothering Department of Commerce

THE question whether or not broadcasting will die out may be bothering some people, but not the United States Department of Commerce. During October, 56 stations were licensed to broadcast, and 22 dropped out. This indicates that the industry is increasing by about 24 stations a month.

On November 3, there were 553 broadcasting stations operating, 19 of them on 400 meters under Class B, and the balance on the old 360-meter wave. During the week ending November 4, eleven new stations were licensed to broadcast.

With the cessation of the Corinth Radio Supply Company's station WHAU, Mississippi comes off the broadcasting map, there now being no broadcasting station in that State. It is the only State, today, without a station. States with single stations are Delaware, Wyoming, New Hampshire, and Vermont—all others having two or more. California is still in the lead. The new broadcasting stations licensed and those discontinued follow:

Supplemental List of Limited Commercial Stations on 300 Meters

- KFFE—Eastern Oregon Radio Co., Pendleton, Oregon, 100 watt.
 WMAZ—Mercer University, Macon, Georgia, 750 watt.
 WPAF—Peterson's Radio Co., Council Bluffs, Iowa, 10 watt.
 WSAS—State of Nebraska, Lincoln, 250 watt.
 WNAS—Texas Radio Corporation and Austin Statesman, Austin, Texas, 100 watt.
 WRAR—Thomas, Jacob Carl, David City, Nebraska, 20 watt.
 KFCE—Moore, Frank A., Walla Walla, Washington, 50 watt.
 KYO—Electric Shop, Honolulu, Territory Hawaii, 40 watt.
 WPAB—Pennsylvania State College, 1 watt.
 WWAC—Sanger Bros., Waco, Texas, 50 watt.

New Class B Station on 400 Meters

- WBZ—Westinghouse Electric & Manufacturing Company, Springfield, Massachusetts, 600 watt.

List of 22 Broadcasting Stations Deleted During the Month of October

- WGAU—B. H. Radio Co., Savannah, Georgia.
 WHAJ—"Daily Telegraph" and E. K. Kitts, Bluefield, West Virginia.
 WHAU—Corinth Radio Supply Co., Corinth, Mississippi.
 WDAT—Delta Electric Co., Worcester, Massachusetts.
 WHU—The Wm. B. Duck Co., Toledo, Ohio.
 WJT—Electric Equipment Co., Erie, Pennsylvania.
 KQT—Electric Power & Appliance Co., Yakima, Washington.
 WPL—Fergus Electric Co., Zanesville, Ohio.

WIAL—Standard Radio Service Co., Norwood, Ohio.

WDAB—H. C. Summer & Son, Portsmouth, Ohio.

WBAZ—Times Despatch Publishing Co., Richmond, Virginia.

Entrants for the "Receiving Record"

EDITOR RADIO WORLD:—I am a reader of RADIO WORLD and am deeply interested in radio. I have noticed from time to time, different articles on reception of broadcasting stations and articles by some one who claims records for receiving.

I am now driving at the article in RADIO WORLD, No. 31, dated October 28, where Mr. J. A. Merklein claims a record and says that on October 16, 1922, he happened to tune out WJZ and get WDAP of Chicago, and WSB of Atlanta, Georgia, on detector tube and 110 volts and two variometers.

I am not claiming any record, as there

are others who may have done better; but I have him snowed in. Kindly ask him to take notice that I use only the detector tube and one coil 4 inches in diameter and 2 inches wide, two variable condensers and only 69 volts.

The following are stations heard clearly any night they are on and the weather clear: WOC, Davenport, Iowa; WSB, Atlanta; WDAP, Chicago; WWJ, Detroit; WLK, Indianapolis; KDKA, Pittsburgh; WGY, Schenectady, New York; WGI, Medford Hillside, Massachusetts; WBAD, Minneapolis, Minn.; WOZ, Richmond, Ind.; WIP, Philadelphia; 4CL, Commerce, Georgia; WJAR, Providence, Rhode Island; WOO, Philadelphia; WGR, Buffalo.

This does not include stations in and around New York City. And also, these stations have been verified. And cold weather has not set in yet for good results.

I am also able to tune out the stations around New York and Newark, if not wanted. That is, if I want WJZ I can tune out WFAF or the opposite, or both, and get WOR.—Walter George McKinley, 47 West 37th Street, Bayonne, New Jersey.

* * *

EDITOR, RADIO WORLD:—We do not claim to beat the receiving record of Mr. Merklein, but think that we are getting excellent results with the outfit we are using: 4-wire L-type aerial, 40 feet long, 25 feet high. 3-coil tuner with two condensers. Receive, Boston, Springfield, Detroit, St. Louis, Davenport, Pittsburgh, and Atlanta—all on the detector alone. Using 3-tube set, we receive Atlanta loud enough to be heard all over the room with Baldwin phones. Chicago, KYW, we are unable to receive with less than three tubes.—Emmett L. Miller, Chappaqua, New York.

Remember "This Is a Radio Christmas"

and that millions of dollars will be spent during the holiday time for radio gifts.

Why not get your share of this business by advertising in the issue of RADIO WORLD of December 9, which will be a

HOLIDAY RADIO GIFT NUMBER?

Thru this medium you can reach thousands of readers, who are not only interested in radio themselves, and want new equipment, but who also will give presents to others whom they wish to make radio fans.

ADVERTISING RATES:

Regular advertising rates in force for RADIO WORLD'S HOLIDAY RADIO GIFT NUMBER, as follows:

\$150 a page, \$5 an inch. Discount, 10% four times, 15% thirteen times. Forms close Wednesday. Published following Wednesday. Classified ads. five cents a word.

Take advantage not only of RADIO WORLD'S circulation, but also its cash-thru-the-mail pulling power.

Be represented in RADIO WORLD'S Holiday Radio Gift Number, and reach the many thousands who actually want your goods and are ready and willing to pay for them.

Preferred Positions Must Be Booked Immediately.

Copy for run-of-paper positions will be received up to November 29.

Answers to Readers

WILL you furnish me with directions to make a loose coupler for the following receiving sets: Two audio-frequency transformers, 3 6-ohm rheostats for filaments, .0005 mfd., variable condenser, grid condenser and leak, lightning arrester, one pair of 3,000-ohm phones. I have 2 tubes, 8 inches long. The diameter of primary is 4 inches and the diameter of the secondary is 3 inches. How many turns to a tap are necessary on the secondary coil?—Morris Siegel, Tacoma, Wash.

For the primary, wind 110 turns on the 4-inch coil, using No. 26 double-cotton covered wire. Use 10 taps of 10 turns each, and 10 taps of 1 turn each. For the secondary, wind on the 3-inch coil, 100 turns of No. 30 double cotton-covered wire, tapped with 10 taps of 10 turns each. Use your .0005 variable condenser across the secondary coil. These coils should give you a tuning range up to 1,000 meters.

I have just finished building a standard short-wave regenerative set, using a vario-coupler of some 60 turns on a primary 4 inches in diameter; and 50 turns on a 3-inch secondary. I am using No. 24 wire on the secondary and No. 22 wire on the primary. My aerial is of the outdoor type, 20 feet long with a 15-foot lead-in consisting of 5 wires. This gives a 100-foot length. There are times when I hear code, but I seldom hear broadcasting. Possibly this is because my aerial runs over a tin roof. What is my approximate wave length? Why can't I hear the broadcasting stations.—Paul Roelser, Baldwin, Pennsylvania.

The inductance of your coupler primary is, approximately, 450 microhenries; and of the secondary, 220 microhenries. To just what wave lengths the primary will tune, is merely guess work. Your antenna, undoubtedly is very poor. Doubling the wire back and forth makes the inductance low, neither can the capacity be very large. The best way is to run the aerial, in one stretch, about 100 feet and keep it clear from the tin roof. Then you may tune to 600 meters. We recommend a .0005 variable condenser across the secondary. With this, you should be able to hear broadcasting.

Let me know the wave length I can tune up to with the following equipment: Vario-coupler, crystal detector, primary with 13 taps of 10 turns each on a 4-inch tube, 23-plate condenser shunted across secondary. My aerial is 150 feet long, 8 feet above the roof of a 4-story house. The lead-in is 10 feet. The fixed condenser is shunted across phones?—Michael McCarthy, New York City.

With such a receiver, you should be able to tune up to approximately 800 meters.

I have just completed a crystal set but can hear nothing in the way of music—only noise. My antenna is of seven-strand copper wire, about 80 feet long. The lead-in is of No. 14 copper, as short as possible. My ground is bell wire and is run over the kitchen floor connecting with the water pipe. Is this O. K.? Is the ground connection the right size of wire?—Francis Molaka, Rome, New York.

There is nothing wrong with your hook-up. It is another case of poor location for reception with a crystal set. Probably you are too far from any of the broadcasting sta-

tions. Improvements on your set might help you. Go over all your connections. According to the Fire Underwriters' rulings, your ground lead must be, at least, No. 14 copper wire. The length of your lead-in should be made shorter.

Is there a broadcasting station in Porto Rico?—Hans Mulinos, Tampa Florida.

We know of one station, WGAD, operated by the Spanish-American Radio School.

Can I use honeycomb coils to load up my aerial circuit to receive Fort Wood? Where should these coils be placed?—Anxious.

You can load up to this wave length, which is 1,450 meters, by inserting a honeycomb coil in the aerial circuit. If you are using a vario-coupler, you will also have to load up the secondary coil. This is, of course, for the plain type receiving set. It cannot be done with your type receiver, as yours is of the variometer make.

I have a two-stage amplifier with a regenerative set. I hear music and speeches at a distance of 50 to 75 feet on clear nights. I

PHANTOM-CIRCUIT

BUILD YOUR OWN. This marvel of mystery, using no aerial, no loop, no ground, brings in music instead of static showers. We consistently hear concerts on Magnavox, even stations 550 miles distant, audible 100 feet from horn. The simplicity of this set will surprise you. No radio frequency. Complete instructions with photo of circuit sent prepaid for 60c.

VESCO RADIO SHOP, Box W-704, Vanville, Calif.

That Armstrong Circuit

So much interest has been displayed in the special article, "TESTED INVENTION OF MAJOR ARMSTRONG AMPLIFIES SET 100,000 TIMES," by John Kent, that appeared in RADIO WORLD No. 13, dated June 24, 1922, the publisher decided to put aside a number of copies for those who were not able to get this issue when published. Copies will be sent, prepaid, on receipt of 15c. or send in your subscription, \$6.00 for one year (12 issues), \$3.00 six months, or \$1.50 three months, and subscription will be started with the issue containing the article about Major Armstrong's Amplifier.—RADIO WORLD, 1493 Broadway

RADIO WORLD IN THE PUBLIC LIBRARIES

Many public libraries throughout the country are sending in their subscription orders for RADIO WORLD.

Librarians evidently have made up their minds that the visitors to their libraries are anxious to read articles about and see pictures of the latest developments in radio when they are news.

If your library has not placed RADIO WORLD on file, tell your local librarian how interesting and important is this once-every-seven-day radio paper.

Address: RADIO WORLD, 1493 Broadway, New York, N. Y.

Answers to Readers
(Continued from preceding page)

wish to add a third step. I have heard that a power tube (U-V 202) will increase the volume of sound better than with an ordinary U-V 201 amplifying tube. Which would you advise? Which is the lowest voltage necessary to operate the plate of the U-V 202 tube? Will an Acme transformer be suitable? Will Western Electric phones stand the strain of the diaphragm? What are the advantages of using a power tube in the last step?—George Siebert, East Orange, New Jersey.

The power tube would give you greater amplification than would the ordinary U-V 201, as it allows much more current to flow through the plate circuit. The 202 tubes operate best with a plate voltage of 350 volts. By lowering this voltage, the results are lowered considerably. The transformer you mention is all right. The phone may not be strained, but why waste such power in a pair of phones when a loud-speaker will give you just as much volume?

* * *

In my circuit of a "super," how should the loop aerial be connected to the set? Is there any special connections from the loop? How can it be used?—George Moering, Glens Falls, N. Y.

Design to show windings, also connections from loop, as requested by Mr. George Moering.

The accompanying illustration shows how the connections are placed on the set you describe, utilizing the loop aerial.

* * *

Where is the broadcasting station with call letters OKYX.—Fred Edwards, Lostine, Oregon.

There is no such call letter assigned to any station as yet.

* * *

In making up the Armstrong superregenerative receiver, I have experienced a "peanut whistle." This sometimes develops into a sound like a hiss or a water fall. My tickler coil, or ball, is 4 inches in diameter wound with No. 24 enamel wire and has about 90 turns. The filter condenser is not affected; neither is the potentiometer which feeds the coupler.—Vincent Galloway, Omaha, Nebraska.

The "peanut whistle" you describe is the correct whistle to obtain. It should not be very strong, but it proves that your oscillating tube is O K; or as we say "She notes." The connections are correct. We suggest that you get the switches on the primary of the vario-coupler at the exact adjustment for 360 meters, otherwise you will get nothing but the whistle. If there is a very great

difference even the whistle will be blotted out. The final tuning will be done by means of the loop condenser and the feed-back coil, which, of course, is the rotor of your vario-coupler. Try changing the connections around on the rotor. It may be that the winding of the secondary is opposed to that of the primary.

Broadcast Bill's Radiolays

By William E. Douglass

FOOTBALL never used to make much of a hit with me; I liked baseball an' shinny, but what I could never see wuz why those fellows had to go out on the field to fight. Why couldn't they put the gloves on, then stand up an' do it right? But last year when I bought this set an' started in to listen to football games sent play by play I saw what I'd been missin'. Now I can tell you every game them college fellers play—you never ketch me very far from my set Saturday. The "Demons" here in Brussels Sprouts are playin' every week; we've trimmed the "Canton Warriors" an' the team from Quivver Creek. The "Tigers" down at Goose Grease Creek were all we had to fear until we played 'em Saturday, the big game of the year. On Fri-

day night I strung some wires right near the home town bleachers to use as an antenna an' pick up the football features as they were bein' broadcasted by Station XYZ, an' that way keep the crowd informed on games they couldn't see. The game between the "Tigers" and the "Demons" wuz the one to tell which team, this year, would be the county champion. So you see it meant a lot for Brussels Sprouts to win an' keep on bein' Champions like we have always been.

Before our game had started I tuned in a sending station to show 'em how my set would work when gettin' information. An' then our boys come on the field, the game wuz 'bout to start so I left Min to mind the set because you know my part whenever there's a big game is to lead 'em in the cheers. I guess that's why our team has never lost in all these years. I led a snake dance on the field between the halves while Min wuz gettin' all the college scores as fast as they come in. She give a kid a dollar so's to telegraph that station to broadcast out our football scores all over this here nation an' tell 'em we were winnin'—had the "Tigers" on the run. Well, sure enuf, they did it fore the second half begun.

IMPORTANT NOTICE:

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patent, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

The New Wireless

I BOUGHT a brand new wireless for the kid,
 And started in to rig it up with vim;
 I stretched the copper wire two hundred feet,
 And bought receivers made to listen in!
 I got a tuner and a finder thing,
 And read a lot about galena point;
 I jabbed the needle and I whirled the knob,
 But couldn't get the outfit into joint!

Then twice I got new batteries and worked,
 And once I caught a faint KDKA;
 It sounded like an SOS from Mars,
 And seemed to be a million miles away!
 I bought a new galena point and monkeyed
 With wires and grounders fastened to a pipe;
 I got a two-way switch to stop the lighting,
 But couldn't get the thing to work just right!

I got a longer wire stretched for receiving,
 And painted the arm-piece with paraffine;
 I got some lead and soldered on the ground wire,
 And licked up wireless dope complete and clean!
 And every night at eight we worked and listened—
 The kid would laugh and I would fume and fret;
 I hate to call myself a wretched quitter,
 But I haven't got that wireless working yet!

—LOUISE HOLLINGSWORTH BOWMAN,
 in "The Times," New York.

\$25.00 Radio Set for \$8.25

FOR TWO WEEKS ONLY

The famous Sidbenel Company offers one of the finest and most complete receiving sets for a beginner for the first time at a remarkably low price. No batteries or vacuum tubes are needed. You will hear broadcasting stations very loud and clear. Every essential with full directions for installing the set is included.

SPECIFICATIONS

Aerial wire—150 feet hard drawn pure copper.
 Insulators—four porcelain.
 Detector—supersensitive galena.
 Cabinet—mahogany finish with hard rubber panel, nickel plated switch points, large switch lever, and binding post.

Receivers—leather head band, special cord, and one supersensitive phone.

Special two weeks only. Price complete \$8.25. Same set with double phones \$11.50.

22 to 500 Volt "B" Batteries

Lasts Five Years
 Recharged From
 Any Lamp Socket

The Sidbenel is a Storage "B" Battery that will last five years of constant use without replacing parts.

It will give continuous service for at least six months before it becomes necessary for recharging. It can then be recharged in a few hours to its original capacity, all ready for another six months' use.

A Sidbenel Storage "B" is something every radioist needs. Think of the money saved by not using dry "B" batteries, which are of no use after they once become discharged.

The Sidbenel pays for itself in six months. It is so ruggedly constructed that rough usage will not harm it. The container is one which is of genuine hard rubber, molded into ten compartments. Size 2½" by 3" by 4½". Every inch of Sidbenel "B" is constructed under our own patents. The plates are especially treated with a newly discovered chemical that eliminates howling and

screaming so commonly found in any other "B" battery.

The Sidbenel "B" is shipped to you partly assembled—all you need to do is connect the plates together, and this takes but ten minutes and is most simple, as instructions are furnished with each battery.

Guarantee:—A two-year written guarantee is given with each Sidbenel Storage "B" Battery. This is your complete protection.

For recharging we furnish a rectifier for AC which costs \$0.25 extra. DC current requires none. Complete with directions:

One Unit, 22 volts.....	\$ 3.25
Two Units, 44 volts.....	7.50
Five Units, 115 volts.....	17.50
Eleven Units, 250 volts.....	36.50
Twenty-two Units, 500 volts.....	69.00

Send for free catalogue on parts, and complete sets, and prices for repairing vacuum tubes.

WHETHER you require two binding posts, a simple crystal set, or one of the standard tube sets with amplifier and loud

MASTER BALDWIN PHONES

AN IMPROVEMENT ON WHAT WAS CONSIDERED THE BEST

Those who know, in the radio world, have always used the Baldwin Phone. It has been ever-present where exacting work was to be done. It was conceded to be eight times more sensitive than any other known phone.

Not satisfied with even such a meritorious article as this, the manufacturers have now produced the Master Baldwin Phone. A 40% improvement in refinement and workmanship. Going still further, they have designed the Clarophone, the most marvellous speaker yet produced. Prices:

Singles, \$9.00 Headset, \$16.00 Clarophone Loud Speaker, \$22.50

THE MOST SENSATIONAL

radio development since the Vacuum Tube. After years of experiment and proof, this genuine fixed Radio detector is now available to amateur and professional operators. Its introduction marks the third GREAT step in the progress of Radio—first the crystal then the vacuum tube and now the wonderful Phonophone. Price, \$3.50, sent postpaid.

The Plot Thickens!

Another Radioist Picks Up Phone Call and Seeks Aid in Solving Mystery

EDITOR, RADIO WORLD:—I am using a detector and tuner made from the blue prints furnished by the Experimenters' Information Service of your city, and have secured wonderful results. Using only one step of amplification I have been able to hear a 'phone station (10 watts), WBAA, a distance of about 475 miles. I have heard 'phone stations in 27 different States and Canada; but there is one thing on which I would like information: Almost every night, between the hours of 10 and 12, I am able to hear telephone conversation between the exchanges of Muskogee, Oklahoma, and Little Rock, Arkansas. The nearest is over a hundred miles distant.

I can hear the operator put her party up and also hear them ring, several times each evening. There is only one point in tuning where I am able to hear this. The first time that this was picked up, I thought it was a broadcasting station, but heard central say, "Number 455 is busy." Every night, for several days, I listened to find out where it was coming from as the telephone company here did not ring this number. Later, I could hear the girl say, "This is the Muskogee operator."

Can you offer an answer to this? I am sending a copy of this letter to the Bell Telephone Company and the Western Electric Company. I would like to know if there is anyone else who has picked up distant telephone talk—not radio.—Howard Fowler, Rogers, Arkansas.

Prize Freak Set

Denver Lad Uses Clothes Line for Aerial and Corncob Pipe for Receiver

ORVILLE GARDINER, seventeen-year-old Dener lad, seems to have developed a freak radio receiving-set that deserves the blue ribbon.

"It consists of a small two-cent corncob pipe, with 40 turns of No. 27 cotton-covered wire wound around the stem. He uses a small pencil-clip for a slider, and has scraped bare the wire where the sliding touches.

He drilled a small hole in the side of the pipe bowl, put a drop of metal in, then inserted a chip of galena, and fastened a piece of copper wire by means of a brad half an inch down from the galena for the catwhisker.

All it cost was two cents for the pipe—the

rest of the set was made from pieces lying around the house.

Using a clothesline for an aerial, he received Denver stations with his corncob set.

* * *

His Home-Made Circuit Brings in Wide Range

EDITOR, RADIO WORLD: I have a radio receiver that I constructed. I am using a hook-up that is original, so far as I am able to ascertain. With this hook-up, using a variometer and varicoupler that I made myself—I picked up, in one night, fifteen different sta-

One-tube hook-up as described by Mr. Wallis in his letter.

tions. I have heard Schenectady, WGY; Denver, Havana, Cuba, Minneapolis, WEAY, WDAP, WOR, WEA, 9XO, KSD, WOC, WMAK, and others—about forty in all.

These stations were heard on one tube only. When I use two stages, I cannot wear my phones with comfort. Using the phones without a loud-speaker, music, at times, can be heard all over the house, on two steps. I am using a radiation U-V 200 with 22 volts on the plate. My set is mounted on old battery-jars cut up into sheets. This makes a good panel. Accompanying this is the diagram for the detector. I would be glad to give further information to any one wishing to try out this diagram.—Joe L. Wallis, East street, Talladega, Alabama.

To Be a Radio Engineer

NOW the real designer of radio apparatus is the radio engineer, says Arthur R. Nilson, educational director, East Side Y. M. C. A., New York City, in "The Globe." He is an electrical engineer specializing in radio work just as the turbine engineer is a mechanical engineer specializing on turbines. Radio engineering requires a very high-grade of school training. To be a success—and being a success means more than just getting away with it—the radio engineer must be able to tackle any kind of a radio engineering job, from the making of a simple receiver, scientifically designed, to the complete laying out of a high-power arc, spark, or vacuum tube, trans-oceanic or continental transmitter. Not only must he be an electrical engineer of high calibre, but he must be of a high type of individual intellectually. Many of the so-called radio engineers are out of jobs for the reason that they are unable to make an approach good enough to land them a job or because they are unable to write an ordinary business letter in ordinary English.

Radio Amplifiers for the Deaf

THE amplification of sound by means of the triode vacuum tube has now passed on from its application to wired and wireless telephony to a means of aiding those of deficient hearing, writes Roswell H. Johnson in Science. Its effectiveness is so great that it promises to be to the partially deaf as great a boon as glasses to those optically defective. The use of the amplifier is sure to expand rapidly in this field, although it will be somewhat impeded by its expense.

The purpose of this, however, is to call attention to the application or applicability of a sound magnifier in various fields of scientific work and industry:

1. For detecting distant underground operations as in mine rescue or military work.
 2. Detecting the approach of a boat, train or automobile before it comes in sight.
 3. Detecting the approach of a storm.
 4. As a parallel instrument of the binocular prism glasses of the ornithologist, to detect bird songs too far to be heard distinctly or at all. It is particularly useful in detecting the higher notes that do not carry far and in observing nocturnal migration.
 5. To aid the hunter in detecting sounds of distant game.
 6. In conversation from vessel to vessel or station to station at shouting distance and a little further.
 7. In directing men aboard or on shore.
 8. To extend the possibilities of the dictograph in detecting evidence of crime.
 9. To make possible addressing larger audiences and distant audiences.
 10. To make it possible for some women with weak voices to nevertheless speak to large audiences.
 11. In accoustical research for the study of subliminal sounds.
 12. The detecting of subliminal sounds from animals not now known to make sounds.
 13. To make more audible the whispers or weak sounds of the sick or injured.
 14. To make communication by weak or injured less fatiguing.
- That commercial equipment of good efficiency is now readily available may not be known to some of those who might make good use of the apparatus.

Claim Flaw in World's Biggest Broadcaster

THERE have been a number of complaints that the world's biggest broadcasting station, WBAY, operated by the American Telephone and Telegraph Company, 24 Walker street, New York City, could not be distinctly heard in the northern part of the city. W. E. Harkness, manager of the station, told a reporter for "The World," New York, that it is impossible to tell just why the broadcasting should prove deficient in this particular spot.

"It may be the fault of this antenna, or it may be the location of the persons who complain," said Mr. Harkness. "There is a theory—radio is so new it is difficult to speak with certainty about any phase of it—that an antenna amid steel frame buildings does not work so well as in the open.

"However, whatever the fault may be, it is a small matter. The plant itself, under the roof of the Walker street building, is a complete success. Recently we have been experimenting with remote control by microphoning to the West street station. This is done without loss of time, clarity, volume or anything else.

"We are still using the antenna on the Walker street building roof at times. Last Friday, we broadcast through it with good results. However, the roof structure is a small part of the plant itself. The actual broadcasting is done under the roof. We could easily put up another antenna, or remove it to some other roof. What difference does it make what roof we use? The plant itself is in this building."

RADIO MAN, eleven years' experience in all sides of the game, capable of constructing, installing, operating broadcasting station of any power, desires permanent connection. Go anywhere. What can you offer? Evans, Momus Pier 48, N. R., N. Y. C.

Are you familiar with all the radio symbols used in the various book-ups published in Radio World? If not, secure a copy of Radio World No. 26, dated Sept. 23. In this issue was a complete table of all important symbols used in radio construction and testing. Send 15 cents for a copy, or \$6.00 per year, and have subscription start with that issue. RADIO WORLD, 1493 Broadway, New York City, N. Y.

September Electrical Exports Showed Upward Trend

PRELIMINARY figures of the Department of Commerce showing United States exports of electrical goods for September reflect the improved conditions which are noticeable throughout the

industry, the total, \$5,238,753 worth, being an increase over the preceding month in the amount of \$487,583. The month's total also compares favorably with that for September, 1921.

Important shipments of power transformers and power switchboards were made during September, the totals, \$499,755 and \$365,348 worth, respectively, exceeding by substantial amounts the heavy export shipments of these classes for August. Motors and motor driven devices also increased over the preceding month, and in general an average improvement of about 10 per cent. is seen in the September electrical export figures.

in Germany, that a law was passed in Britain prohibiting radio amateurs from using instruments and apparatus of other than British manufacture. The regulations went still further and provided that no license would be issued for receiving or sending if even one unit in the installation were of foreign manufacture. This example was closely followed by France, although that country followed a more liberal policy and only recommended the purchase of apparatus of home manufacture for purely patriotic reasons.

It would be interesting, however, to compare the product of German ingenuity and engineering skill with our own American products. For many years that country has been ahead, so far as works of precision are concerned.

Foreign Radio Factories at Work

GERMAN manufacturers and industrialists have not overlooked the great market created in this country by popular radio broadcasting, says Lloyd Jacquet in "The Mail," New York. Accordingly, they have put their engineers to work and have started their factories and begun placing a complete line of radio apparatus for foreign consumption, with the old time "Made in Germany" label.

In fact, the German manufacturers have been able to undersell any other competitor because of the cheapness of labor and of raw products in Germany today. This competition so alarmed English firms, who foresaw the danger of a flooding of British markets with goods made

The Difference

A RADIO transmitter consists of apparatus which can generate alternating current at very high frequencies (from 20,000 to several million cycles per second) in a conductor which, at the transmitting station, is called the transmitting antenna. A radio receiver consists essentially of an antenna which is cut by the field propagated by the radio transmitter, and of detecting an amplifying apparatus whereby the minute currents generated in receiving antenna are detected and made audible.

Union College to Invade New Radio Field

THE Union College radio station, WRL, Troy, N. Y., will make an earnest endeavor to become a pioneer in a new field. It is the intention of the club to become the first amateur station able to carry on regular communication across the Atlantic. In preparation for the work, which will be started in December, the organization is now completing a new apparatus. There will be two G-E tubes of 250 watts each, with the current supplied by a 240-cycle alternator. Since the circuit has no filters, but is self-rectifying, the tone will be the same as a 240-cycle modulated C-W equipment. With the completion of the changes, there will be four or five experienced operators ready to make the tests. Long-distance continuous-wave transmission is the new field in radio work. It is the field which will be explored by the college radiomen in the tests they will make under the auspices of the American Radio Relay League.

Union is famed as the introducer of the wireless baby-carriage two years ago. That novelty received a world-wide broadcast, through motion pictures. The station is remembered also as one of the first in the country to broadcast entertainments. As that field of endeavor is supplied with powerful stations employing factory-built installations, not only far-reaching but expensive in original cost and maintenance, the college radioist will return to experimental work.

Beating the Record!

EDITOR, Radio World: While some of your readers pat themselves on the back and brag about their so-called long-distance records for radiophone-broadcast reception, we would like to give them some real long-distance records to shoot at.

With a 70-foot aerial and a Westinghouse RC set we have received clearly and distinctly the following stations, all strong enough to put on a Magnavox:

WBAR, Fort Worth, Texas; CFAC, Calgary, Canada; KFCB, Phoenix, Arizona; WDAF, Kansas City, Missouri; WWJ, Detroit, Michigan; St. Louis, Missouri, and Chicago.

We have a reliable range here of 1,500 miles and have no trouble in picking up any station of any power on the Coast and as far east as Denver. We have a very good location and a good aerial, so, of course, that has a good deal to do with it.—E. S. Morrison, Ashland, Oregon.

The **Newest Product On the Market**

Our WD-11 Tube Socket. Made of first grade Formica. Can also be used with French Tubes.

Spirola

HIGH GRADE CABINET LOUD SPEAKERS

TRADE MARK

Do not be deceived by our low prices. SPIROLAS are not cheap instruments made to sell at a low price. They are rather a remarkable development made possible by the invention of the SPIRAL tone chamber (patent pending), which not only allows us to market a cabinet instrument of the highest grade in every respect at an almost sensational price, but gives many exclusive advantages over the common cabinet type speaker, which is nothing but an ordinary horn enclosed in a cabinet—great competitors for full-sized tone chamber and a really complete elimination of metallic, "horn" noises. SPIROLAS are especially recommended to music lovers who can appreciate an absolutely pure, natural tone.

We make a complete line—of equally high-class construction throughout, with fine hand-rubbed finishes. **ALL SPIROLAS ARE SOLD UNDER ABSOLUTE MONEYBACK GUARANTEE—ten days to see and try them for yourself.**

SPIROLA CONCERT—Complete with special, powerful built-in cord ready to hook up in place of phones, beautiful mahogany or oak **\$12.50**

Satin black finish, nickel-plated fittings, otherwise same as DELUXE **\$3.85**

SPIROLA DELUXE—New, improved duplex type for use with your headset, two complete speakers in one, eliminating the usual interference between phones, same finish as above. **\$4.85**

We also make the DELUXE and black finish type for use with a single loud speaker unit. In ordering state whether for use with headset or unit. At dealers or postpaid (C. O. D. if preferred).

Write for booklet with suggestions for testing and adjusting Radio Sets. Thousands now in use give absolute satisfaction.

Pignolet Instrument Co., Inc.
114 Liberty Street, New York, N. Y.

Something Brand New in Antenna Wire

Jobbers and Dealers—Stock this now for Fall Trade

Here is an Antenna Wire that will at once appeal to the radio enthusiast. It has a real selling argument in that it is different and better than any makeshifts to date.

This new wire, hard drawn from the finest copper, has a corrugated surface with 10 collecting points on its circumference. This gives a greater collective surface and the points give a greater gathering surface.

The result is extreme sensitiveness, and an increase in the range and clearness of any set, from the simplest crystal type to the finest V. T. Receiver.

Packed in neat cartons of 100 feet, 200 feet and 500 feet.

Price \$2.00 per hundred prepaid

Where Radio Kept Vigil Armistice Day

(C. Underwood & Underwood, N. Y.)

Washington, the nation's capital, city of "magnificent distances," always athrill with the echoes of the men who made American history, has no more appealing place in all its vast area than Arlington Cemetery, where rest forever the brave men who gave their lives in the cause of liberty—not only for their own native land, but that the rest of the world also might be free. Perhaps there is no more beautiful, peaceful spot on earth than these hallowed acres where sleep the dead of the United States Army and Navy. The rows and rows of modest milestones of the privates and the massive memorials of their officers are, today, a foreground for the gigantic towers that support the aeriels of NAA, the government's radio station at Arlington. Nothing is more silent than these high-pointing towers, nothing marks more specifically the grandeur of science and the mystery of life. So one may be pardoned, if in their steadfast position as transmitters and receivers of all that is wonderful and new in the world, they should be described as the watchers of our soldier dead, particularly as, year by year, Armistice Day becomes a day of reverence. For all time, the President of the United States will be expected to place a wreath on the grave of the Unknown Soldier, on this occasion. Arlington Cemetery with its verdant slopes and sleeping dead on one side, the silent-flowing Potomac River and the busy farms on the other, the great City of Washington to the south, and radio's lofty masts towering over all is a picture no American who loves his country should fail to appreciate.

Using Jacks with Vacuum Tubes

THE use of telephone jacks in a receiving set has become a standard practice. They provide a convenient and rapid means of shifting the receiver from one stage to another. They can be connected so as to cause the insertion of the plug in any stage to light only those filaments required for that stage of

amplification. Removal of the telephone plug can extinguish all filaments and permit their relighting by the mere insertion of the plug without readjustment of the filament rheostats. Because of this completely automatic lighting and extinguishing of the filaments through the use of proper filament-control

jacks, the life of the vacuum tubes is greatly increased and the drain on the filament batteries is reduced to a minimum. It is always a safe proposition when employing vacuum tubes—whether a 6-volt tube, a "peanut," or 1½-volt tube—to use the filament jack. In the long run, it is the best with a receiver.

DX Hook-ups for the Radio Novice

By George W. May, R. E.

MANY believe that stations sending out the longer waves may be heard at great distances because of the greater wave-length used. It seems to be fairly well established by experiment that long waves do travel with somewhat less attenuation than short ones, but there is no experimental evidence to show how much better the long waves are propagated than the short ones. Recently low-powered stations sending on 200 meters have been successful, occasionally in transatlantic communication, a result previously thought impossible. The reason that the longer wave stations are heard at greater distances is due to the fact that they are high-powered stations. It is difficult

Schematic Diagram of a simple, compact receiving outfit. A variometer is used as a means of inductance. The plate-battery voltage is 22 volts. Drawn by George W. May.

to send out large amounts of power at the shorter wave-lengths because of the necessarily small antennas used at the short waves.

There is apparently much difference in signal strength at different parts of the season. Sometimes signals—between a pair of stations with the apparatus the same in either station—show the variation in strength as much as four to one, the stronger signals being received in the winter time. It has been suggested that summer foliage absorbs a considerable amount of energy from traveling waves.

There is also a pronounced difference between night and day transmission. Signals generally travel much farther at night than during the day; but transmission at night is likely to be more variable than it is during the day.

It seems that, during the winter months, there is not much static, or disturbance, in the receiver, so that comparatively weak signals should be received. If a broadcasting station is sending out one kilowatt of power a

tube detector, such as is shown in the accompanying sketches, should give readable signals at a distance of several hundred miles. This distance will naturally depend largely on how good an antenna is used at the receiving station and how well the set is grounded.

It will be noted that distances greatly in excess of this are reported, but generally a tube receiver is not used, as shown in the accompanying sketches. By proper coupling of the plate and grid circuits of the tube a regenerative action is obtained which may increase the sensitiveness of the receiver a hundred times in the hands of a skillful operator.

On a number of occasions the writer has copied signals in his laboratory from stations several thousand miles away, using only one tube. Let us consider just what must take place in order to catch the ether waves and make them audible. Some arrangement must be utilized to catch a portion of the waves as they fly through the air. Such an instrument is usually in the form of what we know as an aerial or antenna. As radio waves have definite frequency, or wave length, some means must be employed to tune the receiving set to the incoming waves, or adjust it so the waves in the receiving instruments will oscillate in synchrony, or harmony, with the waves of the transmitter. The instrument of synchronization takes the form of a tuning coil, loose-coupler, variometer, vario-coupler,

variable condenser, or, sometimes, a combination of several of these instruments.

I intend to utilize the variometer as a means of inductance for the 360-meter stations. The circuit is simple enough for any novice to work out. If connected up according to the diagram wonderful results should be obtained. From New York City I may say that I have heard WGY, Schenectady; WSB, and KHJ, also stations in Chicago, Cleveland and Detroit.

The second sketch illustrates the adding a one step of amplification to the circuit. A D-L coil No. 50 can be used in place of the variometer, but I recommend the variometer in order to have some adjustments.

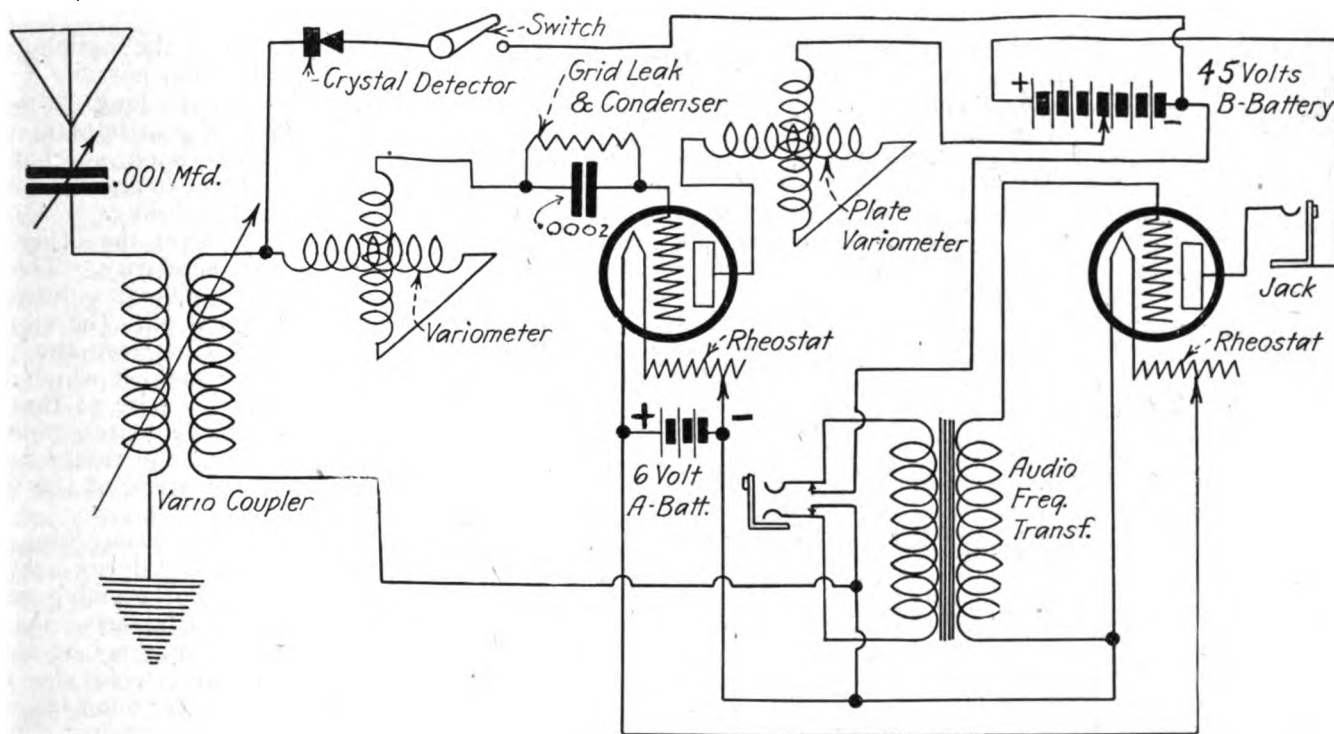

The sets and circuits described are simple and comparatively inexpensive; but it must be remembered that crystal detectors cannot be used for the results I claim no matter how sensitive the crystal may be. Crystals are good for twenty-five miles on the broadcast material, although greater distances can be had under favorable conditions. Code messages may be received over hundreds of miles with crystals. In using this circuit I would recommend using the W-D-11 vacuum tube, known as the dry-cell tube, operating on one dry cell. Believe me, these are the tubes for receiving! They are new on the market. If connections are made properly there is no reason why signals cannot be copied for some distance, provided the aerial is at least 100 feet long.

The amateur wishing to try out the circuit described by Mr. May in the accompanying article will secure satisfactory results by following the above hook-up. Note that a one-stage amplifier is used, which adds to the audibility of loud signals. The instrument of synchronization takes the form of a tuning coil, variometer, loose-coupler, variable condenser or, sometimes, a combination of several of these instruments. Any novice can easily work out this circuit, as it is very simple. Connect it up carefully according to the diagram. A duolateral coil may be used in place of the variometer, but Mr. May recommends the variometer because of the adjustments. Drawn by George W. May.

Combination Hook-up of Detectors

By Fred. Chas. Ehlert

Complete schematic diagram of a vacuum-tube detector outfit with one-step amplification as described by Fred. Chas. Ehlert in the accompanying article.

ONE of the most important parts of a receiving set is the detector. It is important in this respect: The human ear cannot receive signals above 10,000 cycles of frequency. In radio work the frequency sometimes runs as high as a million cycles, so means must be provided for making such high-frequency signals audible to the human ear. The detector does this. Therefore it is necessary to get the best results from detectors.

There are a number of detectors in use at the present time. They are the crystal, the magnetic, the Fleming valve, and the audion- or vacuum-tube. Crystal detectors are of different types: they are manufactured of various minerals. Galena is one of the minerals used mostly by amateurs. The

operation and assembly of a galena detector is simple. Crystals must be kept clean in order to retain their sensitiveness. Washing with a little alcohol greatly improves them if they have been left standing, or have been handled, for a long time.

The accompanying diagram illustrates the complete schematic diagram of a vacuum-tube detector outfit with a one step of amplification. A crystal detector is included also in the circuit. The amateur should try out both detectors separately. The hook-up shows both detectors in the circuit. When using the vacuum tube as a detector, care must be taken that the switch in line with the crystal detector is open. If the crystal is to be used, merely close the switch, shut off the rheostat on the

detector tube and adjust the crystal. With the aid of the one-stage amplifier, it will make possible the amplification of signals. Many amateurs would rather use a crystal detector than a vacuum tube because there is less battery noise and distortion. Others, however, prefer the vacuum tube as a detector; so, for these amateurs, the vacuum tube may be placed in action and the detector crystal eliminated. With the aid of an extra stage of amplification, signals will be amplified to a certain degree of sensitivity.

A novel effect would result if both detectors were lined and each one tested out separately. This would give an idea as to what both detectors do. It is an interesting experiment for amateurs.

Over 600,000 Hear "Aida" by Radio

Verdi's Great Work Is Broadcast Successfully With Metropolitan Singers and Orchestra

By Patrick Nichols

"AIDA," Verdi's grand opera, was heard by radio, on Armistice Day, it is estimated, by over 600,000 people within a radius of a thousand miles. The performance was given by members of the Metropolitan Opera Company and the Metropolitan Opera House orchestra, in oratorio form, in the Kingsbridge Armory, New York, the largest armory in the world, where over 15,000 persons

assembled to hear the performance. While the rendition marked a high spot as the program of the Armistice Day Festival in the Bronx, New York City, it will go down in history as one of the most important radio events of the year. Those who tuned their receivers on the 450-meter wave-length of WEAf, the huge broadcasting station of the American Telephone and Telegraph Company, will be proud, in years to come, to tell about this first "radio performance" of one of the most popular grand operas ever written. Voices and instruments were heard with remarkable beauty and clearness.

No effort was spared by the broadcasters to ensure reproduction of the opera by wireless without distortion.

Engineers of the American Telephone and Telegraph Company spent a week in the armory making tests. They were handicapped by their inability to hold a rehearsal, but, as an alternative they personally sang in different parts of the huge armory to assure themselves that the average human voice could be reproduced with fidelity. They also experimented with a half dozen canaries to make sure that the amplifiers would catch even the finest phrasing of the Metropolitan singers.

Commenting on this remarkable achievement, "The American," New York, says: "Such glorious broadcasting successfully accomplished, it looks as if popular musical pleasure and general musical culture were really 'in sight.'"

With the Ossiphone Even the Very Deaf May Hear Radio

RADIO is wonderful to all who can hear, but what about the poor fellow who is deaf and can't hear a sound of the concerts which flood our ears? Does he think radio so fascinating? Ordinarily not; but with a little instrument, the "ossiphone," even the totally deaf who have not heard a sound for scores of years, may listen in at the radiophone. The ossiphone may be the means of bringing a chest of gold to those who formerly had not even a penny.

It is a simple instrument, in-

By Ortherus Gordon

vented by Mr. S. G. Brown, of London. It is not a means of amplifying sound so as to overcome all degrees up to total deafness; nor does it translate sound into some other medium of communication, like motion or color. It conveys sound to the brain without the aid of ears, eyes, tongue, or touch; but it does enlist the aid of the bones. It is just what the word says—a bonaphone; "ossi" is Latin for bone.

In appearance, the ossiphone is a small ebony box, possibly 1 inch high and 4 inches long. From a slot in one end protrudes a metal vibrator with a knob, so that the entire instrument looks like an enclosed telegraph-key. Double wires leading from the other end heighten the similarity. The resemblance disappears, however, when the cover is off. The vibrator is seen to pass between the poles of a horseshoe magnet which have been wound with wire so that the ossiphone is made to resemble the inside of a telephone receiver with a bar vibrator instead of the usual diaphragm.

For use with a radiophone, the wires of this useful device are connected to a radio receiving set in place of the headphones. A deaf person, perhaps, may not be able to operate a radio set, for he must hold his ossiphone in one hand while he presses its knob against a finger knuckle of the other. Strange as it may seem, he hears exactly the same sounds as a listener-in, who can hear, with a headset. The difference is this: he hears through his bones; the other hears with his ears.

Remarkable tests made in London demonstrate that a person with normal hearing can actually hear better over the radiophone by use of the ossiphone than by use of the ordinary headset. It is claimed that the bones make better ears than the ears themselves!

In explanation of this, it seems that sound is not a product of the ear alone but the effect of the ear's vibrations on the brain. The aural nerves are the ones that do the trick. If vibrations could be transmitted to these aural nerves by any means whatever, hearing would result. In an event of this kind, the ears would be merely passive appendages.

This strange condition has actually been brought about by the ossiphone. That instrument utilizes the bone as a medium through which to transmit sound vibrations to the aural nerves and thence to the brain. The use of the ossiphone is neither nerve racking nor unpleasant. The bones themselves do not tingle—the vibrations of the ossiphone are too delicate for that. The only sensation to a deaf person is the joyous one of perfect hearing.

Plain Dish as Loud-Speaker Distributor

The lowly china, or earthenware, dish, such as may be found in any home kitchen, makes a surprisingly good distributor for a loud-speaker. Take one earpiece from your headset and suspend it in front of and facing the dish after it has been put end upwards on wood or some resonant material. By careful testing you can find the exact spot where the sound is the loudest, then the phone may be permanently suspended or fastened, as is shown in the photograph. Surprising mellowness will result. The experiment is well worth trying when you are picking up loud stations. In the photograph, 1 shows the disc, or plate, in position; 2 is the telephone earpiece; 3 is the rheostat to increase the brilliancy of the vacuum tubes; 4 is the dial that governs the tuning qualities; 5 is the receiver complete.

Merchant-Marine Officers of Future Must Know Radio

By S. S. Smith

IT has been decreed by the State of Massachusetts that the education of a merchant-marine officer is not complete without a knowledge of radio. Accordingly, the Massachusetts' State Nautical School, the steamship "Nantucket," is offering to cadets, this winter, a complete course in radio operating and engineering. This is a departure from the ordinary curriculum; for during past winters, at North End Park, Boston, the education of prospective merchant-marine officers has been limited to navigation by the sextant, the log, lead, and compass, fair winds and the grace of heaven.

Now, for the first time, merchant officers in the making are being fortified against storms, currents, and fogs at sea by timely instruction in the use and operation of all kinds of radio apparatus. The importance of this instruction may be judged by the fact that there are at present only two training ships supplying our merchant ships with officers of American parentage: the "Nantucket" of Massachusetts, and the "Newport" of New York.

There is a special instructor on the "Nantucket" whose duty is to teach the cadets the Continental Code and to explain radio navigating. Fascinated youngsters are learning that there are other ways of obtaining a position at sea than those given in the nautical lore and navigational tables of Bowditch. Study of the radio compass is stressed, as that instrument is of greater value to the seafarer than any other.

During the winter lay-up at the dock, the theory of the science will be taught. In the summer, when the "Nantucket" goes on her annual cruise halfway around the world, the cadets will get actual practice in the radio room of the ship. In this period, they will have demonstrated to them the possibilities of radio navigating—not as it is practiced now but as it may be practiced in the future.

This is the first step ever taken to weld the deck and the radio department of merchant ships. Heretofore, there has been jealousy and ill-feeling—old-timers have felt that radio is an encroachment on their methods. They have balked at using radio. The Navy long ago

The Massachusetts State Nautical Schoolship "Nantucket," photographed at Algiers, aboard which students are given a complete course in radio operating and engineering.

brought radio within the control of the navigator; but then radio, as a means of battle signaling, was far more important on war vessels than on cargo and passenger carriers. Some time may pass before radio as

taught aboard the Massachusetts' school ship will have a visible effect on merchant marine, but the fact remains that future officers are being prepared for radio dominance on the sea.

Radio-Wire Tables

By Frederick J. Rumford, E.E., R.E.

No. 2 — Single Cotton-Covered Wire

Showing the Number of Feet in a Pound and Fractions of a Pound

APPENDED is the second of a series of five tables which the radio amateur will find useful for many purposes. The succeeding tables—"Double Cotton-Covered Wire," "Single Silk-Covered Wire" and "Double Silk-Covered Wire"—will be published in early numbers of RADIO WORLD.

Size	¼ lb.	½ lb.	¾ lb.	1 lb.	1 lb.

This table can be used for a variety of purposes.

Radio Waves Penetrate Earth

Experiments in Mine Indicate That Radio May Be Used for Communication

By Carl H. Butman

WASHINGTON, D. C.—The well-known signals KDKA, East Pittsburgh, have been heard in many places throughout the country, but it is doubtful if it was heard 100 feet below ground and at a distance of eighteen miles from the station, until the Bureau of Mines experts heard it recently in a test made in a mine at Bruceton, Pennsylvania.

Although the tests were hurried, only short continuous waves being used and no attempt made to modify the apparatus so as to try out longer waves, the experimenters found evidence that electromagnetic waves may be made to travel through solid earth.

Reporting to the Bureau of Mines, C. L. Colburn, C. M. Bouton, and H. B. Freeman, jr., say that, in response to many requests for a device permitting the use of radio in mines in the interest of safety, especially following disasters which frequently break mine telephone systems, they recently undertook an unusual experiment, in co-operation with three engineers of the Westinghouse Electric Company.

In their official conclusions they state:

"The present preliminary experiments, while unsuccessful in indi-

cating any practical method of using wireless waves for underground communications, nevertheless indicate clearly that electromagnetic waves may be made to travel through solid strata. The 'absorption,' or loss, of intensity with distance is very great for the short wave-lengths used in these experiments. Longer wave-lengths are known to suffer less absorption and may possibly be found practically effective under certain conditions."

The preliminary experiments consisted, first, in receiving signals from without the mine at Bruceton by means of a receiver located inside; and, second, both sending and receiving messages underground through the strata. It was found that with a receiving instrument set at a point 100 feet underground, signals from KDKA could be heard distinctly. About fifty feet from the receiving station used in this test was a six-inch bore-hole from the surface, lined with iron pipe and containing electric light wires which extended therefrom throughout the mine. The presence of these wires evidently assisted greatly in the reception, they report, for, when the receiving set was carried to another point removed from wires and tracks, the signals were barely audible through

fifty feet of cover. "The fact that signals were detected, however, even though faintly, is sufficient evidence of transmission through the ground to encourage further experimenting," they state.

In sending waves underground, the Westinghouse 20-watt vacuum-tube transmitter was used in such a manner as to send out continuous waves from 200 to 300 meters length; but they say that additional experiments with waves of increased length are much to be desired. It was found that although signals could be heard distinctly through fifty feet of coal strata, the audibility fell off rapidly as this distance was increased.

In all experiments, the vertical antennae was found to give the better results, the horizontal antennae giving practically no reception. A loop of a single turn was used, however, with fair results. All these experiments were tried with a wave-length from 200 to 300 meters, except the reception from KDKA which was 360 meters. The strata at the experimental mine lie almost horizontal, and may have had some influence on the transmission of radio waves; but the present experiments gave no conclusive evidence on this point. They seem to agree that the degree of wetness of the strata influenced the transmission of radio waves. The mine was a comparatively dry mine, but the overburden of soil and soft shale is damp, and a small stream of water is continually flowing from the mine. The underground workings of the Experimental mine follow a horizontal five-foot vein of bituminous coal, and the transmission and reception inside the mine followed the course of this vein.

In order to gain a quantitative idea of the transmission of the radiated energy, a milliammeter was inserted in the plate circuit of the receiving apparatus. This normally read 1.6 milliamperes, but the flow of radiant energy from the receiving antenna produced more or less depression of the current according to the intensity of the signals. This then made possible a comparison of the intensity of the reception at different points. The milliammeter was graduated in tenths of a milliampere, and tenths of a division could be estimated by eye. Signals could be clearly heard when the inflowing energy was too low to be indicated by the meter; that is, the clearly distinguished words from KDKA gave no appreciable depression of the plate current.

New Voice Amplifier at WEA F

New York's newest radio-broadcasting station, WEA F, operated by the American Telephone and Telegraph Company, uses a "voice amplifier," as shown in the photograph at the right. This is necessary because the music studio and the broadcasting station are a quarter of a mile apart. The new amplifier is a masterpiece of delicate mechanism that will pick up the notes of a bird and start them on their journey over the air without losing the most intricate trill. WEA F was the station through which the opera, "Aida," was broadcast on Armistice Day—a radio event that marked a new era in science and music, for it proved to the world that, because of price or distance, the masterpieces of music may now be given to everyone by voices accompanied by an orchestra that only a few have had the great pleasure of hearing. Without the voice amplifier, the success of such an undertaking would be questionable; but this new device is able to convey, without losing even the fraction of a sound, music and the human voice—from any place where they may be produced—to the broadcasting apparatus. Every week records some startling new addition to radio's remarkable equipment that makes it more and more of a great service to all the people.

(C. Kadel & Herbert)

Why Radio Transmission Is Superior to Wire Transmission

By *B. R. Cummings*

Radio Engineer. General Electric Company

RADIO may be defined as: "A system of communication whereby intelligence is transmitted with the speed of light in all directions, for any desired distance, without the aid of any artificial medium, by the propagation and detection of electrical disturbances in space."

An analysis of this definition will indicate the unique inherent characteristics of radio which make it serviceable where other systems of communication cannot be applied.

While the speed of transmission in radio is no greater than that of wire-communication systems, it is equal to it. A radio message travels at the rate of 186,000 miles per second—more than one million times the speed of sound. A radio message, for example, which is transmitted in New York is received at San Francisco in *less than two one-hundredths of a second!*

A radio transmitter will radiate its message in all directions, a characteristic which has made broadcasting possible. A broadcast message can be heard by airplanes, by ships at sea, by submarines submerged in the sea, and in mines or other points under the surface of the earth.

So far as we know radio communication can be effected over any desired distance. Radio stations have already transmitted completely around the world, and, since the medium which transmits light to us from stars and planets is the same medium which transmits radio communications, it is reasonable to believe that a radio message may be propagated through space for a distance depending only on the amount of power which is put behind it.

The third inherent characteristic of radio—that is, its ability to transmit intelligence without the aid of any artificial medium—places it in a field absolutely its own. Not only does this permit communication with points otherwise inaccessible, such as, for example, aircraft, with ships, and to inaccessible spots on land, but it eliminates the need of securing rights of way for transmission lines and their construction and maintenance. A radio system is therefore rendered more positive than wired systems in that it is not subject to the failures which frequently occur during the winter months in wire lines.

While the means utilized in radio differ entirely from those used in other forms of communication, it is possible to connect a radio system to a wire system so that a telephone subscriber, sitting in his home, may talk by a wire line to a radio station, where his voice is transferred to a radio transmitter, transmitted by radio and again transferred to a wire system. This fact makes it possible to extend the range of wire-telephone systems over areas which were heretofore considered impassable by including in the wire-telephone line a radio link which bridges the previously impassable section.

While a radio communication is broadcast in all directions, it would be desirable for some classes of work to be able to transmit only in one direction.

Senatore Marconi, during his recent visit to the United States, made a plea for further investigation into the possibilities of directive radio-transmission whereby the message would be transmitted in one direction only. He pointed out that, in his early experiments, he had succeeded in transmitting directly over short distances by using a reflector at the transmitting station whereby the propagated waves were reflected and concentrated in one direction similar to a beam of light from a searchlight.

It should be remembered that it is

not intended that radio communication shall replace the wire-telephone system. Its use will be restricted to communication between points where wire communication is not possible or applicable. This is due primarily to the fact that the number of radio communications which can be carried on simultaneously in a given area is limited, whereas in wire telephony the number of simultaneous communications which can be carried on is unlimited.

While directional radio-communication is needed in commercial radio work in order that radio may be made to approximate more nearly the directiveness of a wired system, such development will be intended not to replace wired systems, but to eliminate unnecessary interference in areas not lying between transmitting and receiving stations and to effect power economies in the transmitter itself. It should be remembered that, while broadcasting by radio is serviceable in communicating with moving stations and for broadcasting work, commercial radio traffic is usually handled between fixed stations—that it would be desirable to be able to transmit from one to the other without having the message broadcast.

The foregoing has referred briefly to the characteristics of radio-communication without touching upon the functioning of the apparatus itself. Many people witnessing for the first time a radio transmitter in operation are disappointed, for there is no visible motion in any of its parts. It is noiseless, and there is no evidence whatever of the phenomena occurring in its various circuits.

Its operation, however, includes a consideration of both the infinite and the infinitesimal; infinitesimal units of electricity so small that they cannot reflect light, and, therefore, can never be seen, moving under perfect and complete control of the operator; amplifying the human voice millions of times without distortion and transmitting it through space with almost infinite speed. In analyzing the phenomena involved and the almost unbelievable future for this method of communication we may probably be forgiven for modifying Morse's memorable message: "What Hath God Wrought?" to "What Hath God Not Wrought?"

Eleven New Broadcasters

ADDITIONAL broadcasters licensed during the week ending November 11, as limited commercial broadcasting stations, on 360 meters, are as follows:

KFED—Billings Polytechnic Institute, Polytechnic, Montana.

WNAQ—Charleston Radio Elect. Co., Charleston, S. C.

KFCK—Colorado Springs Radio Co., Colorado Springs, Colo.

WNAX—Dakota Radio Apparatus Co., Yankton, S. D.

WOAJ—Ervin's Electrical Co., Parsons, Kansas.

WNAW—Henry Kunzmann, Fortress Monroe, Va.

WBAQ—Lyradion Mfg. Co., Mishawaka, Indiana.

WNAV—People's Tel. & Tel. Co., Knoxville, Tenn.

WRAY—Radio Sales Corporation, Scranton, Pa.

WPAL—Superior Radio & Tel. Equipt. Co., Columbus, Ohio.

WOAF—Tyler Commercial College, Tyler, Texas.

The Radio Primer

*For Thousands of Beginners Who
Are Coming into Radio Circles*

Weekly A B C of Radio Facts and Principles Fully and Tersely Explained

By Lynn Brooks

DOES everything, or certain things only, contain electricity?

Everything contains electricity. And everything means just everything—your shirt, your pencil, your shoes, your hat, yourself! This is similar to the fact that most everything contains water. Take apples and peaches, for instance. If the water is evaporated we have dried apples or dried peaches. If we could withdraw the electricity from an object there is no doubt that the object would change in some way.

* * *

How about the movement of electricity?

Electricity makes itself known only when it is in motion, or when there is more than usual, or less than usual, of it in an object. This is exactly what air does. If air moves we have wind. We speak of electricity in motion as a current of electricity just as we speak of a current of air or a current of water.

* * *

Are there any polarities to electricity?

In order to answer this question let us consider what happens when we comb our hair and hear a crackling sound, or the fact that the hair is attracted toward the comb when it is near it but not touching it. This is due to the presence of more than the usual amount, or less than the usual amount, of electricity. In order to more clearly understand this try the following experiment: Take a piece of cork about the size and shape of a pea and cover it with a layer of tin-foil. It will then be shaped like a ball. Fasten this to the end of a silk thread about eight inches long and hang it up. Take a piece of hard rubber—a rod is best, but a comb will do—and a piece of cat's fur, or flannel, and rub the rod with the fur. This should be done in a room containing dry air, as damp air lets the electricity leak away. Any room that is heated will answer. The rod now contains more than the usual amount of electricity. It is electrified. You electrified it when you rubbed it with the fur. When a body contains more than its usual amount of electricity it is said to have a negative, or minus (—), charge. The fur, which had a

When a current is passed through a coil of wire, millions of lines of magnetism radiate from each wire, winding and twisting about the coil.

less amount, is positive, or plus (+).

* * *

What can be said of the positive and negative charges in regard to attraction?

Positive electricity repels positive electricity; negative electricity repels negative electricity; positive attracts negative electricity. In other words, like poles repel; unlike poles attract.

* * *

Will electricity flow through any material?

Charge a large ball with positive electricity and another large ball with negative electricity. Take a silk thread and extend it from one ball to the other. Then test the two balls to see if they are charged. You will find that there is no change in them. Both still have their charges. Instead of using the silk thread use copper wire. Test the two balls and you will find that neither is charged. When we used the silk nothing happened.

* * *

What is the explanation of this?

What happened is this: The excess electricity on the negatively charged body went through the wire to the positively charged ball, which, you must remember, had less than the usual amount. In other words, we had the electricity moving along the wire, forming an electric current. The wire permitted electricity, but the silk

How to Put Up Your Aerial

A SIMPLE way to raise an aerial mast of a considerable height is to plant a shorter staff about one-third of the length of the main aerial-mast close to the base of it, and raise the larger mast by means of block and tackle. Guy ropes should be slung from the mast about two-thirds the way up, to permit of guiding.

It is customary to make the aerial of more than two spans of wire so that a greater conducting-surface will be presented. For stations up to one kilowatt in size, an aerial should have at least six wires spaced not less than two feet apart nor more than three feet apart. It has been found that nothing is gained by placing the separate spans closer together than two feet; for fairly large aerials, three feet is good spacing.

Other things being equal, the greater the height of the aerial the greater its range either in transmission or receiving; but the range is largely influenced by the number of strands in the aerials. Where the height is limited, the aerial may be extended so that it covers a considerable area.

It must be kept in mind that as more wires are connected parallel to the aerial, it will tend to give it greater activity. The capacity inherent in it is also directly increased. The aerial must not be made too large for the transmitting set or there will be a decrease instead of an increase in the range.

thread did not. Then the wire is a conductor of electricity and the silk a non-conductor. An object that will not conduct electricity is known as: 1—non-conductor (not a conductor), 2—di-electric (not electric), 3—insulator (to shut off).

* * *

Are conductors needed for electricity?

A conductor is absolutely needed for a current of electricity; so is the object to which it is connected. In order to explain further my example of an electric current: We rubbed the hard rubber rod with the fur, and this rubbed some of the electricity of the fur into the rod. The electricity that we rubbed on the rod is not something new or unknown. It is electricity that simply moved from the fur to the rod in very small parts, called electrons. These electrons have been measured, weighed, and are able to show themselves. It is these moving electrons which makes a current. Of course, to have a continuous current we must keep them moving.

No Interference Between 360 and 400 Meters

By *Washington R. Service*

FOR some time the Department of Commerce Radio Section has insisted that there was no actual interference between the broadcasting stations using a 360-meter and a 400-meter wave, if good sets were used and properly tuned, and this contention recently has been proven. The radio inspector at San Francisco has submitted a report to the Radio Section of the Department of Commerce, which, it is believed, will be of interest to the radio public. Because of numerous complaints in California that serious interference was experienced by listeners-in while two neighboring stations were transmitting simultaneously, one on 360 meters and one on 400 meters, the radio inspector conducted a personal test which he describes as follows:

"I arranged a test with a single-coil tuner and also two inductive tuners located at a point midway between both transmitting stations. These stations, which were about a mile apart, were then requested to transmit at exactly the same time. It was found that with the single-coil tuner it was impracticable to separate the two waves. However,

by using an inductive tuner, a charge of six degrees either way, would tune out either one of the stations. This corresponded to a change of about six meters on either side of the transmitting wave.

As the receiving station was located on almost a direct line between the two stations mentioned, it seemed to demonstrate, beyond any possible doubt, that, with a selective tuner, it would be entirely feasible to receive from either station at will without interference from the other.

No doubt there will be much complaint from single-coil receivers and from other stations having very large aerials; but it is thought the interference will result in the ultimate improvement of receiving apparatus throughout the district. A campaign of education is being instituted by the Broadcasters Association; and it is intended that an inexpensive form of resonance trap is to be placed upon the market, for installation in conjunction with single-coil receiving stations, which will enable operators to reject unwanted signals, within the range of 300 to 600 meters.

Radio from Two Important New Angles

By *Arthur G. Shirt*

THERE is danger to the politician in radio—a danger that, apparently, he does not see. It loses votes faster than it gains them.

The correspondent of a New York paper, during the recent gubernatorial campaign, struck the idea right when he wrote:

When a voter can sit at his home without the influence of the crowd, and calmly analyze the speech of a political candidate as it is delivered, I am inclined to believe that it is very disadvantageous to the speaker. Candidate _____'s talk, as it came in over the radio, was a fine example of pure, unadulterated "bunk," and when I heard the band play and the crowd cheer, I then realized how easily the average voter is beguiled into believing that he has heard some concrete important statement that means something, when he is really only being

influenced by the general effect of the meeting.

Radio is extremely impersonal—it is neither coerced nor influenced by any personality, good or bad. It strips everybody and everything to the same level—forces them to substitute real genius and honest arguments for fake cleverness and "hot air." With this analytical coldness in its favor, it is a wonder that radio has not been used in courts of justice where the emotions of juries are too frequently played on by designing lawyers to gain ends not always coincident with the ends of justice.

Of course, it sometimes happens that the human element in the case before the jury for trial must temper the decision and alleviate the

National Radio Week
Dec. 23 to 30, Inclusive

CANADA is anxious to join the United States in celebrating National Radio Week. Harry Lewis, editor of "Radio News," Toronto, has written to Major J. Andrew White, chairman of the Executive Committee, 328, Broadway, New York, that his country is willing and ready to affiliate. He believes that the concerted action of both countries would have a good effect on radio in general. Every effort will be made to bring the Canadian fans and amateurs in line.

Dr. Alfred N. Goldsmith, eminent radioist, inventor, and chief of the radio department of the College of the City of New York, has been appointed chairman of the Committee on Radio Engineers.

"The Evening Mail," New York, says editorially:

MOVEMENT is on foot to organize a "National Radio Week." This is good and commendable and deserves the support of everyone interested in or connected with the radio industry. If the idea develops into more than a threat and is actually carried out it will do much toward stimulating business.

Incidentally The Evening Mail suggested a similar plan in these very columns last August that should show The Mail's attitude pretty closely.

If the sponsors of the present movement can show some interesting action, they can rest assured that the columns of this paper are at their disposal.

There is another movement on foot to raise \$50,000 among the manufacturers to advertise radio on a national scale. All these movements are good, but they should have been planned months ago. Instead manufacturers sat and waited until the last minute for something to happen, confidently expecting that radio was so good that it would sell itself to the public with practically no effort on their part. This theory has been exploded and now we have desperate last minute methods, which are always more or less haphazard, to revive the industry.

The best thing in the world needs selling power behind it and radio is no exception. We have a market before us as big as all outdoors.

If the manufacturers do raise \$50,000 for an advertising campaign, let us hope that it will be spent wisely. If half of this sum was expended on programs and the other half on advertising the programs, no doubt the radio industry would receive a much needed impetus.

punishment. More often, however, is it necessary to administer stern and impartial judgment. If the jury does not see the prisoner or the lawyers, but hears testimony and arguments by means of a radiophone, will it have a better chance of rendering a fairer decision than otherwise possible? Here is a question that may puzzle the minds of economists, thinkers, jurists, and criminologists for some time to come.

Whatever value this suggestion may have, the use of radio as a relentless mirror will warn politicians and others who use it for their own ends that the radiophone is a dangerous toy for them to play with.

How to Make an Intermediate-Wave Regenerative Receiver with a Wave Length from 150 to 3,000 Meters

By Joseph Schuck

THE panel is 18 inches long and 6½ inches high. It may be bakelite or hard rubber. The shielding in front of the condenser and inductance may be copper or aluminum. It is connected to the ground terminal of the set. Care must be taken in shielding the panel as the plates must not touch the shaft of the variometer or any metal parts of variometer or condenser.

The condenser is a 43-plate .001 mfd. and is inserted in the antenna. The variometer must have a rotor ball measuring 3½ inches over all. A cardboard tube is used measuring 4 inches inside and 4 inches long. It should be given a number of coats of shellac to prevent it from shrinking after it is wound. The winding is bank wound, 3 layers, 87 turns to a layer started ¼

Hook-up for the regenerative receiver, 150 to 3,000 meters, as described in the accompanying article.

inch from the end and 11 taps taken off the first tap at 3, the second tap at 5 and 8 thereafter. Two taps are taken off the variometer at the stators as seen

by the drawing. The inductance is then mounted on the variometer by means of two small V brackets. Care should be taken when mounting. The winding of the inductance must run in the same direction as the variometer winding. The rotor of the variometer must also be able to pass freely when turning at the inductance.

The audion socket is to be mounted on a shelf by means of set of V brackets. The shelf is of hard rubber, or bakelite, 4½ inches long and 3 inches wide. Three battery posts are also mounted on this shelf. The rheostat is mounted directly under the socket shelf, thus saving space and giving the set a better appearance.

The phone condenser, C 3, is an .0025 mfd. The grid leak and condenser is combination type, .0005 mfd.

Front view of set showing wave-meter at right

Rear view of set, explained in diagram at the right.

Schematic design of the rear view of Mr. Schuck's circuit, as shown in the lower photograph at left. The bank-winding system, Mr. Schuck believes, should be welcome to all amateurs. This receiving set has a true wave-length from 150 to 3000 meters. In a test of its range bringing in broadcasting stations, the results were as follows: WJZ, WGI, WGY, WOR, WEAF, WVP, and KDKA—quite a string. In code stations, Mr. Schuck claims, there is no limit to its distance. It has brought in eight district stations, clear as a bell. Its furthest distances, so far, are Station's NAO and NAP, located in Florida. Mr. Schuck's station is in New York City.

The Meaning of Potential

By Harold Day

THE word "voltage" has been used to indicate electrical pressure. Other terms are used, and it will help us in our understanding of electricity and in reading scientific books if we have some knowledge of these terms. We speak of an "electrical potential" and "difference of potential." "Difference of potential" is the same as "voltage." Potential is the voltage (difference of potential) between any body and the earth.

The earth is such a large body that its electrical condition is always con-

stant. It is a fairly good conductor, and any loss, or excess, of electrons on its surface is quickly equalized. Thus we can use it as a reference point from which to make measurements. Its potential is always zero. "Potential" is to electricity what "level" is to water. The zero point for measuring water is, of course, the sea level. If one tank of water is 180 feet above sea level, and another tank 160 feet above sea level, their difference would be 20 feet.

In other words, there would be a

20-foot head of water in order to make the water flow from one tank to the other. In this same way we speak of an object as having a potential of 180 volts compared with the earth. Another object may have a potential of 160 volts compared with the earth. Their difference in potential would be, as stated, 180 minus 160, or 20 volts. There would be 20 volts pressure to make the electrons flow from one object to the other. This difference in potential, or voltage, is known as electromotive force—Emf.

The Vacuum Tube

Its Action and Proper Use. Correct Method of Caring For It

By Donald Van Wyck

TO understand the action of a vacuum tube it is necessary to know the following facts:

A current of electricity is simply a flow of electrons. The electrons flow in one direction, forming a current which is said to flow in the opposite direction.

Electrons are small charges of negative electricity.

All materials contain electricity—positive and negative.

It has been discovered that metals, if heated, will throw off into space some of the electrons which the metals contain; that the hotter the metal up to a certain degree of heat the more electrons it discharges. Electrons travel at a high rate of speed. If air or any other gas is present in the space around the metal the electrons strike the minute particles of the air, or gas, and are soon stopped.

The above facts are applied to the vacuum tube. The air is pumped from the tube—hence the name "vacuum"—so that the passage of the electrons will not be stopped. The filament marked F in a tube is heated so that it becomes red or white hot. This is usually done by an electric current furnished by a storage battery. G represents the grid, and P the plate.

The vacuum tube is the only part of the more common radio receiving-set which requires replacement. It is therefore important that the amateur have a correct understanding regarding its use. A detector, or amplifying tube, is nothing more than a highly evacuated incandescent lamp containing a plate, grid, and filament. Thomas A. Edison made his first tube by inserting a wire in the top of an ordinary electric-lamp. The principles which apply to the care of lighting lamps apply equally as well to the tubes.

Only after scrapping a tube or two does the amateur realize that he has a delicate instrument with which to contend. It is certainly a delicate instrument, for a very slight increase in filament current may prove fatal. The difficulty is introduced by the necessity of operating the tube so near its danger point. Very few people realize this.

By a slight turn of the filament knob the fine tungsten-wire is brought to a glow, or, as we say, a brilliancy. The melting point of tungsten is 3350 degrees centigrade. This is higher than any other substance except carbon. Iron melts at 1550 degrees centi-

grade. Melting of the filament occurs when the battery is fully charged. When six or more volts are impressed across the terminals of the filament of the tube a rush of current passes to the filament, taking the chance of burning it out. To eliminate this some type of resistance is used in series with the filament and battery. Some of the more common type of vacuum tubes are designed and made to take less voltage.

There are several types of rheostats which may be used with the vacuum tube. One of these types is the wire-wound rheostat. This has been widely used, but has many defects. Few amateurs understand its proper use. Sometimes when the broadcast doesn't seem to come in just loud enough he will force the rheostat up a peg or two. He does not realize that a very slight increase in current decreases the life of the tube, and the chances are that it will burn out.

Another defect of the wire-wound rheostat is the method of bringing the filament to its proper operating-temperature. This is done by gradually increasing the current until it reaches the required luminosity. Contrary to popular conception, this is not the proper method of turning on a vacuum tube or any other tungsten-lamp. A tungsten-lamp should be turned on so

How Mica Is Mined

MICA for diaphragms comes almost exclusively from the Far East. India contributes the most of it, but some is mined in Africa. It is found far under the ground, frequently enclosed by granite or other hard rocks.

When a mica rock is discovered, natives build a fire on it and continue it until the rock is thoroughly heated. Water is then thrown on the heated mass and the sudden temperature change opens up cracks along the "grain" of the rock. Crude wedges are then driven into these cracks and the rocks split apart. The pieces are loaded into native baskets and hauled and dragged to the surface.

Only a small proportion of the mined mica is satisfactory for diaphragms. Sometimes less than one-tenth of one per cent. can be used. To be a success in reproducing sound waves the mica sheets must pass laboratory tests for elasticity, toughness, resistance to heat, high electric strength and transparency.

Mica in itself is not magnetic, in fact its insulating properties are of a high order. To be successful as a diaphragm the mica must be aided by a flat disc of soft iron fastened firmly to the mica at the exact center spot over the magnets.

Schematic chart showing the graph of a battery after the tube has been in operation. Note the difference of the battery voltage as compared to the hours of power consumption. Suggested by Donald Van Wyck. Drawn by S. Newman.

that it instantly flashes to its operating temperature—but not above it! Burning the lamp below this temperature causes the filament to crystallize and break when subjected to slight vibration.

Tungsten, if examined under a microscope, would appear to the eye as a structure similar to a bundle of wires. Tungsten must have that structure in order to make it ductile and strong.

Regarding the amplifier. If you will study investigations you will find page after page about the structure of tungsten and the intricate method of obtaining that ductile structure. You will learn also how the proper structure is lost if the filament is used improperly. Heating the filament to a temperature of 200 degrees centigrade below the proper operating temperature changes the fiber structure of the metal to a block structure. The filament, if examined under a high microscope, will look as if it contained a small train of cubes. The comparison is like the old story of the strength of a bundle of twigs compared to a single stick.

Fortunately we need not worry about all of these changes in the tungsten in our ordinary lamps every time we turn on the light. The question is asked: "Could we use this same idea for lighting the vacuum tubes?"

The problem is a little different. The device used in the power-house is expensive and bulky. But a more simple device is made which bids fair to fulfill the requirements of the radio novice, especially for radio work. The automatic current adjuster dampens the current when it tends to increase, and vice versa. It also permits flashing of the tubes to their proper operating temperature, thus causing the prevailing crystallization of the filament. In other words, it is designed to operate the tubes under proper conditions, irrespective of the condition of the battery or tubes.

With the DX Night Owls

From a Non-Radio-Frequency User

EDITOR, RADIO WORLD: In **RADIO WORLD**, No. 31, dated October 28, I noticed a letter concerning an evening record of reception, by Mr. J. A. Merklein, 7513 Third avenue, Brooklyn, New York, in which his greatest distance was about 800 miles.

I beg to submit for favorable comparison the following record for one evening, most of which was made over an Aeriola Senior set, using an aerial 196 feet, including lead-in, single wire, hung 50 feet in the air, ground on water pipe. Part of this was made on a double circuit, regenerative tickler, using one-stage amplification. A home-made set.

PWX, Havana, Cuba, 820 miles; then followed, in order, WLAG, Minneapolis, 825 miles; WGY, Schenectady, N. Y., 1,026 miles; WGI, Medford Hillside, Mass., 1,090 miles; and at 10.10 p. m., Central Time, I closed with station KDYS, located at Great Falls, Montana, 1,667 miles. I have logged 54 stations, all over 250 miles from Birmingham, and would be glad to compare this record with any other amateur, who is *not* using radio-frequency.

Come on you amateurs, step up and get your feet wet.—Kenneth F. Smith, 133 Francis St., Birmingham, Alabama.

* * *

16 Stations on 80 Degrees of Dial

EDITOR RADIO WORLD: The records I have made in receiving no doubt have been equaled by others with half the radio or audio-amplification; but I doubt if many can equal what I am doing with one detector-tube without any amplification. I built my apparatus, and although I have two steps of audio-amplification which I use with a loud-speaker when I wish to entertain friends, I have been experimenting for some time to see just what can be accomplished with one tube only. Many fans refuse to believe the results of my work, but I have proved it to others who have visited me.

While experimenting on my home-made receiver, I have heard, in the past few months, concerts from over a hundred different stations located in 30 different States of the Union, also Canada and Cuba, 2,250 miles air-line to California, 1,350 miles air-line to Denver, where I get two stations quite regularly. I have heard three stations in Texas—Dallas, Houston and Fort Worth—also WBPA regularly, about 1,150 miles air-line. I get PWX, Havana, Cuba, most every Wednesday and Saturday night, about 1,250 miles air-line. I get all southern and western stations regularly.

All of this has been accomplished on a detector tube without amplification. I have even listened to WOC, Davenport, Iowa—about 575 miles air-line—without amplification or antenna. My apparatus is so finely adjusted that, on a test, (with others present) when weather conditions were good, I made the following record:

In about 20 minutes time, I tuned 5 different stations at 400 meters, 5 different stations at 360 meters and 6 stations between 360 and 400 meters, clean and clear, without any interference. One would hardly think that stations supposed to be at 400 and 360 would vary

that much; but they do according to how I check them up. I got 400 meters at from 20 to 22 degrees, and 360 meters at 14 to 16 degrees, on the wave-length dial of my receiver. It is almost impossible to turn the dial sufficiently by hand, so I use the rubber at the end of a lead pencil to lower the edge of the dial, by twisting the pencil. By this method, I can turn the dial to a hair.

In this 16-station test, after the receiver was adjusted and set for reception of first station, all I had to change for the stations following was the wave-length dial or secondary condenser. Result: 16 stations on 80 degrees of dial.

The foundation of my apparatus is the 3-circuit honeycomb-coil design with some important changes in various places. However, I get results.

At present, I am the official eastern outpost testing station for WSB, Atlanta, Georgia, and we have been of mutual benefit to each other. WSB is one of the best on the air and about the correct distance—550 miles air-line—for good testing. I have used their broadcasting for a standard to build a machine of which I am very proud.—H. S. Rahrer, Box 43, Crafton Station, Pittsburgh, Pa.

Something to Brag About

EDITOR, RADIO WORLD: The following is of no small moment, and will be of interest to other radio fans, especially those who have broadcast their success through your columns:

I have an MR-6 De Forest, two stages of amplification, a Magnavox, 2-strand antenna 75 feet long and about 25 feet high. Thursday morning, November 9, I received a letter from Harry Davis, playing at the Lyric Theatre, Atlanta, Georgia, asking me to tune in at 400 meters for WBS, Atlanta "Journal," Thursday night November 9, at 11.55, when there would be broadcast a message to me at my home in Hollis, Long Island, and that he would also warble a song for me. If I succeeded in tuning in for WBS the Atlanta "Journal" wanted me to take down the program and immediately telegraph them of my reception. After playing around an hour with local high-powered stations and many long-distance stations, among which were Louisville, St. Louis, Chicago, Detroit, Cincinnati, Indianapolis, Davenport, Milwaukee, Minneapolis, Pittsburgh, Buffalo, Washington, Fort Worth, and many others, finally, at 12:05, I got WBS loud and distinct, but feared it was too late to receive the message that was to be broadcast to me. However, I hung on and, at 12:45 the message came, and the song followed, the program concluding at 1:10 a. m. I immediately sent a night lettergram diagnosing the program and messages broadcast to Panama, Kansas City, and other places, as proof of my fine reception and, the following night, the result was broadcast by radio and published in the press.

Saturday night, November 4, I received, loud and distinct, a program from PWX, Cuba. Have had several stations in Texas several times. My set is most sensitive. I have received the voice 3,000 miles and have had France and Germany on code. With the additions I am making, I fully expect to receive the human voice from across the ocean in the near future. One advantage I have, I am able to tune out all static. I did this during the summer. I am able to tune out

all nearby high-powered stations for the reception of long-distance programs.—L. R. Ault, Seminole Avenue, Hollis, Long Island, New York.

* * *

Hears Denver in Maine

EDITOR, RADIO WORLD: Sometime last May, I forget the exact date, a local amateur operating a Westinghouse R-C set picked up part of a concert broadcast from the Reynolds Radio Company, Denver, Colorado. I consider this quite a record as the conditions were only normal and the transmitter was not of very high power.—Maxwell K. Murphy, 2 Orange Street, Eastport, Maine.

* * *

DX without Antenna

EDITOR, RADIO WORLD: I state here with what I believe is a record for long-distance receiving, without using some form of antenna.

On the evening of November 2 while listening to a fine number from WBAP, rendered by the Oil City Jazz Band, I had considerable interference and decided to close the station for the evening. Not thinking, I disconnected my antenna before cutting off the battery circuit. I was somewhat surprised to find that WBAP's program then came in exceptionally good. This brought on some experimenting and I found that I could easily tune in stations WHB, KSB, WGM, and WBAP.

On the evening of November 3, the experiment was repeated and I tuned in the following stations, WGM, WDAF, WWJ, KDKA, WSB, WHB, WOC, WHAS, KSB, and WOS.

My set is a simple home-made affair with U-V 200 detector and two stages of audio-frequency amplification.

This information is positive and I am ready at any time to produce my witnesses or repeat the experiment.

In order to ascertain whether or not the set was in any way connected with the antenna, I disconnected all wires, moved the set ten feet from any outside wires and the results were the same.

I would be glad to have your opinion on this matter, and will also be glad to hear from any other station that can duplicate the feat.—E. M. Pace, 423 Farmer Street, Vicksburg, Mississippi.

* * *

A First-Night Record

EDITOR, RADIO WORLD: With the hook-up suggested by Mr. W. Miller, as published in **RADIO WORLD**, I have received, very clearly, KDKA, WEA, and all the Philadelphia stations. This has been accomplished with a hurried hook-up without soldered joints. Also, I have had no trouble tuning out stations from 360 to 400. I think that with using a vernier condenser, I will get much better results. I accomplished the above the first day I hooked-up, using only old material I had around.—R. L. Jones, jr., Lanerch, Pennsylvania.

* * *

On Detector and One-Step

EDITOR, RADIO WORLD:—I have noticed Mr. Merklein's claim of a record for receiving. On a detector and 1-step of my own make, I have received such stations as KDKA, Pittsburgh; Louisville, Kentucky; WOC, Davenport, Iowa; the Sweeney Auto School, Kansas City, Missouri; KYW, Chicago; WSB, Atlanta, and, also, on October 29, at 10.30, I heard a station call letters ending with X, Havana, Cuba.—E. Garbutt, 56 Clark Street, Stapleton, Staten Island, New York.

Radio and the Woman By Crystal D. Tector

"DON'T be late with your 'copy' for our issue of November 25th," the editor of RADIO WORLD wrote me the other day, and as I looked at the date on his missive, I was somewhat startled. "That means that Christmas is only a month away," I said to myself.

Only a month away—just thirty days more and the glad season with all its blessings and happy burdens will be at the peak of its celebration. And I must frankly admit that I haven't made a single thing—either with knitting needle or sewing machine—things that women usually start early in fall and seldom finish—and I am not worrying.

The popular slogan, "This is a radio Christmas," I have nailed to my door. There is going to be a big surprise in store for Friend Husband, however. Heretofore, I have given him cigars and neckties; but, this year, I intend to present him with a new radio set—because I want another set so very badly myself! When he sees it in his stocking, he will frown and say a few things under his breath; but when I explain that I need this new set because I am intending that my present layout shall be used exclusively in a little country bungalow we are fitting up for summer, he is going to be perfectly satisfied and congratulate himself on having so clever a wife.

At any rate, I say to all mothers—and all fathers, too—if you do not know what to give your boys and girls this Christmas, do not overlook radio. Get them interested. It will keep them home. It will educate them. It will bring them the proper sort of friends. It will fascinate them. And a radio set is something that is not played with for a few days or weeks. It is something that one will grow more interested in as time passes—something one will want to improve and study and make a part of his very life.

I have already helped a number of mothers who are planning radio sets or parts as Christmas gifts—and I cheerfully offer my services to any others who may be in need of information regarding prices, just what to buy, the why and wherefore of different radio elements, why certain things are needed for certain sets—and so on. I have made a very thorough study of all things pertaining to radio, of all the different goods on the markets; and I have even read about every book on radio that has come from the press. So, I feel, I am in a position to help you this Christmas—and I offer my services cheerfully.

Whoever thought of the slogan, "This is a radio Christmas," hit on a happy idea; but I would rather have said, "This is to be the first radio Christmas." You will find that the Christmas of 1923 and the Christmas of 1924 and every Christmas thereafter will be even more radio in atmosphere. Next year will be more remarkable from a radio point of view than this year. And radio will continue to grow and grow until it becomes so much a part of our lives that we will not be without it under any circumstances. When grand opera and baseball and football and every big public event is as accessible by radio as it is through the daily press, only the people who are behind the times will be without it.

And I want to tell you all that I heard the broadcast of "Aida," by the Metropolitan Opera Company and orchestra. All I can say is that if I had shut my eyes, I would have imagined myself in the "golden horseshoe" of that favored place. The rendition lost none of its beauty coming over the ether. In fact, it seemed to me that it was particularly beautiful. Everything—from the deep diapason of the bass instruments to the thrills of the soprani and the birdlike notes of the flutes—came through with wonderful charm. A woman friend whom I had invited to listen in, who had never heard a grand opera in her life, was thrilled almost to tears. She never could have afforded the price of an admission, and for the first time in her life, her deep-rooted love of music was partly satisfied.

Miss Mary T. Jackson, of New Orleans, writes me to advise her regarding C batteries for radio-frequency. After reading her letter carefully, I will ask her to read my answer herewith just as carefully.

Do not interfere with the set that is giving you such good results unless it is to add another stage of radio-frequency. The 201 tubes should be used for the amplifying circuits and the 200 tube only in the detector. C batteries are not used in radio-frequency, as the job of putting a negative potential

"Ara," Most Elaborate Radio-Equipped Vessel Afloat

(C. Kadel & Herbert, N. Y.)

The "Ara" played her part in the World War in the French navy. Later she was purchased by Mr. W. K. Vanderbilt, of New York, refitted from stem to stern, and is now ready for a long cruise in the South Pacific Ocean. Perhaps the most important part of her equipment, however, is the elaborate radio apparatus which Mr. Vanderbilt installed regardless of cost. This yacht, now flying the American flag, is more thoroughly equipped for radio transmission and reception, it is claimed, than any other vessel afloat—more so, even, than Senatore Marconi's famous "Electra."

on the grid of the amplifying tube is taken care of by the potentiometer across the A battery. In radio-frequency amplification there is no step-up ratio in the transformer. The primary and secondary are of the same number of windings. The transformer merely passes along the amplified output of one tube to the next tube of the further amplification.

Whisper! The editors let me have a peek at the Christmas cover for RADIO WORLD, the other day. It is a beauty—warm and cheering and full of the radio-Christmas spirit. You must not miss it. The big Christmas number will be out on December 9.

Latest News-Ph Week

(C. International News Reel)

(Above) With no provision made for tuning, a receiving set must, perforce, be of a low order of efficiency. Furthermore, all signals come in at the same time, if several transmitters are working in the immediate vicinity. Such receivers are possible, but are never brought into practical use, due to the fact that they have no means of controlling the wave-length. Usually the beginner starts off with an arrangement of this sort. In the accompanying illustration, a receiving set of this type is shown, built on a rubber heel. It employs a mineral detector, with outdoor antenna and water pipe as ground. It was constructed by George E. Johnson, of Minneapolis, Minnesota, at a cost of \$1.35, exclusive of the receiver. Mr. Johnson claims that he can receive with this make-up within a range of about ten miles.

(C. Kadel & Herbert)

(C. International News Reel)

(Above) One of the most important elements in radio is the inductance coil and the transformer. These instruments make it possible for us to hear the long-distance transmitting stations. Due to the many fine wires in the transformer, it is necessary that they be wound with absolute correctness. By hand would be a tedious and tiresome job. In the photograph, a machine is shown by which Miss Alma Stark winds the transformer or inductance coils. Note the spools of wire at the right of the machine. These spools of magnet wire are of two different sizes—one is of a coarse size, which makes up the primary winding; the other is of a finer wire, used on the secondary. Transformers, due to their peculiar winding, must be given the utmost care in their manufacture, as one error in winding will cause the transformer to function in an unsatisfactory manner.

(C. P. & A. Photos)

(Above) Dr. Royal S. Copeland, who, on March 4, 1923, became State Senator from New York, is a radio enthusiast. He is in the photograph giving his son, Royal S. Copeland, Jr., a lesson in radio.

Photos of a Busy in Radio

(C. Kadel & Herbert)
 (Above) Reverend Francis Duffy O'Laughlin, of Fordham University, New York, is one of the original radio fans of the United States. He believes that the future of radio is unlimited. He early saw the great possibilities of the new science and it is largely due to his efforts that Fordham University possesses so elaborate and perfect a radio equipment. It was one of the first universities to use radio in broadcasting and receiving, particularly athletic events. During the football season, it has proved that radio is the long-looked-for necessity in disseminating news of important games. The photograph shows Reverend O'Laughlin seated at the Fordham radio-receiving station.

(Above) This photograph shows how phonograph music is picked up and broadcast by microphone and broadcast. It is part of the radio equipment of station WJZ, Newark, New Jersey. This equipment, together with the skill of the operators there, is responsible for the great distances it covers and the quality of its transmissions. This photograph shows operator George E. Oliver broadcasting a phonograph selection and gives a good idea just how it is accomplished. The sound leaving the phonograph horn is picked up by the microphone, then carrying it into the modulator, shown on the right. From there it goes into the speech amplifier, shown on left of modulator, and thence to the aerials.

(C. Kadel & Herbert)

(Above) Testing the quality of loud speakers by means of the latest equipment, that photographs defects. To test the quality of loud speakers an elaborate layout of scientific apparatus is necessary. The photograph shows how this testing is done at Columbia University, New York. J. G. Aceves, research engineer, is testing the quality of various loud-speakers for manufacturers. The sounds produced by loud-speakers is picked up by the small special-type microphone shown, then the microphone passes these sounds on to the oscillograph, where these loud waves are photographed. The slightest distortion or any other defects will be shown.

(C. Kadel & Herbert)

(Left) Former service men become radio experts at free radio school. The radio school of the Knights of Columbus, New York, has over a hundred students, the majority of whom are ex-service men. The photograph shows one of the radio classes receiving instruction in wiring a Marconi receiver. The men are taught how to operate and build all forms of radio equipment.

Radiograms

Latest Important News of Radio Garnered from the World Over, and Reduced to Short Wave-Lengths for the Busy Reader.

OVER fifty stations have qualified in the final tests between this country and Great Britain beginning December 12. When reports from the outlying districts have been received over a hundred contestants will be enrolled. A number of stations have already been logged by British amateurs, confirmation reports having been made on stations 2 HJ, Harold Hasbrouck, Port Chester, N. Y., and 2 ZK, George Cannon, New Rochelle, N. Y., and it is expected that many others will be confirmed. From the results obtained so far, and from the interest shown in the preliminaries, it is certain that the coming tests will comprise the greatest amateur event in radio.

A lighthouse station on the Maine coast reported to the district office by telephone that a large can buoy had broken adrift and was moving away. A radiogram was sent to the tender working on buoys, a few miles away. The buoy was recovered and returned to its place before sunset. Radio saved the buoy and probably a day's steaming of the tender. It also safeguarded shipping by promptly replacing the buoy on station.

Dr. Charles P. Steinmetz, research engineer of the General Electrical Company, running for engineer and surveyor of the State of New York, on the Socialist and Farmer-Labor tickets, polled a surprisingly large vote in the recent election. In the midst of a Democratic landslide, supposed to be unfavorable to "scratched" tickets, he polled 207,000 votes, 144,000 more than the candidate of his own party for governor. Dr. Steinmetz did not leave his laboratory to make a campaign. He spent no money. He lost the election, but the large number of votes he received indicates the value placed by men and women on sheer ability. He is one of the most distinguished inventors, scientists, engineers and radioists in the world.

Dr. S. W. Stratton, for twenty-one years the director of the Bureau of Standards, has been elected president of the Massachusetts Institute of Technology, in Boston. This institution will give a four-year course in radio engineering, and is the first college in the country to inaugurate such a course in that branch of engineering.

WGY will tell the story of the Harvard-Yale game, at New Haven, by means of a telephone line running from the press section of the Yale bowl to the transmitting equipment of WGY. Mr. William McGeehan, sporting editor of "The New York Herald," will describe the game. You will hear his voice and his description will be literally on the heels of the runner, his voice will be on the ball as closely as the eyes of the players. In addition to the speaking microphone into which Mr. McGeehan will pour his story, one microphone will be placed in front of the Crimson cheering section and another in front of the blue. At intervals during the game, the cheering section microphone circuits will be switched on and the radio audience will get the atmosphere of the big game.

Radio's Big Place in World

Dr. Lee De Forest Says It Is Now an Absolute Necessity in the Home.

ALL radio enthusiasts may well take pride in the fact that the present tendency in the radio field is away from the amateur experimental stage," said Dr. Lee De Forest in his greeting to the Boston Radio Exposition. "The reason for this is plain. In the short period of less than one year since radio has taken hold of the American public, we have seen a most remarkable acceptance of radio as a means of communication. This acceptance on the part of the American public is nothing short of marvelous. Science has again demonstrated in radio that it can perform miracles for the benefit of the human race.

"Radio has enriched the lives of countless thousands who are not in a position to attend concerts and operas in the leading centers of the country. Radio,

however, has gone far beyond the province of the amusement stage and will, I venture to say, go down in history as one of the few revolutionary devices bringing happiness and joy to countless millions in the way of educational instruction, entertainment and as a means of distributing the news of the world to the people in their home."

Marvelous Developments Include Radio

Navy Communication Service Handled 3,750,000 Words by Radio Last Year.

AERONAUTICS and the radiotelephone are, perhaps, the most marvelous developments of a marvelous age," said Rear Admiral William A. Moffett, chief of the Naval Bureau of Aeronautics, U. S. N., speaking over the radiophone from NAA, Arlington.

Admiral R. E. Coontz, chief of operations, who broadcast a speech in the

"The New York Herald" radio reports of the Harvard-Princeton, Yale-Princeton football games, as broadcast through the General Electric Company's WGY station, were heard clearly and greatly enjoyed by radio fans over a wide area in the East. The "Herald" received a number of congratulatory telegrams from a wide range of territory. The Brompton Pulp & Paper Co., Sherbrook, Quebec, wired: "Details of game very much appreciated."

Perfection of apparatus for insuring the secrecy of radiotelephone and radiotelegraph messages was claimed recently for a French electrical engineer, Edouard Belin. The apparatus is called "radio-cryptotele-stereographe," or "crypto-telestereographe," according to whether it is used for radio or the ordinary telegraph. The instrument is different from Marconi's to direct waves to a given point. It resembles a safety-lock. Sending and receiving instruments, each of which consists of six concentric disks, are perfectly synchronized. The disks each contain a notch and may be moved at an angle in relation to each other. A lever falling into the disks causes rotation of the cylinder and valves a given space between the notches to reproduce the message, which is received according to a code analogous to Morse's, but is reproduced in letters and figures. To keep listeners-in from deciphering the values used between stations, a simple arrangement is added whereby false signals, which do not affect the cylinders, but which cannot be distinguished by outsiders from real messages, are being constantly sent when the instrument is not in use.

The Chicago Opera Company has decided to broadcast its productions.

Leading scientists of Norway propose to install a series of radio observation stations around the North Pole so that the air currents from the polar regions may be followed and the centres of conflict with the warm southern currents determined. Such polar outposts would be of great importance when a regular daily weather forecast becomes necessary for the North Atlantic in connection with aviation service from Europe and America.

Radio messages were sent by automatic machinery at a rate of between 80 and 100 words a minute by the White Star liner Majestic to the station of the Radio Corporation of America, at Chatham, Massachusetts. This speed is about four times as fast as ordinary operators can send and receive, while the greatest speed made by the most expert senders is about thirty-five words a minute. The speed is nearly as fast as that at which messages may be sent by wire, and may open a vast new field for usefulness. The value of radio in handling transcontinental and transatlantic news has been reduced by the slow pace at which messages could be sent, but this new device, it is expected, will obviate this.

interests of the Marine Exposition in New York, said that among its activities the Navy Communication Service handled 3,750,000 words by radio for the American Merchant Marine in the past year.

"During the winter months," he said, "the Naval Communication Service handles on an average of thirty SOS distress calls a month, or one a day." That the value of this service to the American public as a whole, and to shipping interests in particular, cannot be over-estimated, he insisted.

He also mentioned the developments of the radio compass, or direction finder, and stated that the Navy has established stations equipped with this apparatus at various points along both coasts of the United States near the entrance to harbors. When a ship is approaching one of these harbors in a dense fog and is uncertain of her position, all that is necessary for her now to do is to ask two or more radio compass stations for her bearings.

Latest Radio Patents

Figure 1 is an elevation of a complete grid electrode of the invention of Mr. John H. Payne; Figure 2 is an enlarged perspective on one end thereof; Figure 3 is a still further enlarged detail view of a small portion; Figure 4 is a detail view of a modification.

Grid Electrode Structure

No. 1,432,411. Patented, October 17, 1922. Patented: John H. Payne, Schenectady, N. Y.

MR. PAYNE'S invention is, in simple terms, a structure for a grid electrode made of a large number of turns of wire of small diameter which will be self-supporting, and which will be so arranged that adjacent turns of the wire will be maintained in desired spaced relation to one another. In such a structure there will be no necessity for welded joints between the different elements for maintaining them in their proper spaced relation.

Radiotelegraph Coupling

No. 1,432,438. Patented, October 17, 1922. Patented: Joseph Bethenod, Paris, France.

MR. BETHENOD'S invention relates to an improved system of coupling between radiotelegraphic communication and a high-frequency alternating-current generator of the type of those susceptible of furnishing directly a current necessary for feeding the antenna. This station comprises in combination a high-frequency alternator in which the armature winding is divided into sev-

Schematic diagram of Mr. Bethenod's radiotelegraph coupling.

eral Sections not comprising any direct electric-connection between them, and a complex of transformers magnetically independent of one another; the number of transformers being equal to that of the sections of the armature. The primary windings of the transformers are inserted in series in a circuit alternately with the sections of the armature, and the secondary windings of these transformers are connected to the transmitting antenna in a suitable manner.

To Increase Discharge

No. 1,432,867. Patented, October 24, 1922. Patented: Mervin J. Kelly, New York, N. Y.

MR. KELLY'S invention is to increase the amount of power which may be applied to an electron discharge device while still keeping within the safe limits of temperature under which the electrodes can function; to eliminate the objectionable effect which is sometimes produced in electron-discharge devices, namely "blocking," which is caused partly, at least, by undesirable secondary emission from the grid; and to eliminate the effects upon the operation of

Mr. Kelly's invention comprises a preferably evacuated bulb to which the usual base portion is attached. This base portion provides a support for suitable terminals.

electron discharge devices which the lodgement of particles of the filament coating upon the grid have caused.

An important feature of this invention comprises the provision of a black coating on the electrodes of electron-discharge devices, particularly the plate and grid.

Electron discharge devices have been deficient in their operation in one respect because only a limited amount of power could be handled by them without heating the electrodes beyond a safe temperature. By increasing the capacity of the electrodes to radiate heat faster, we can increase the power applied and still keep the temperature within safe limits.

No Wireless Receiving Set is complete without

MAGNAVOX products are designed in our own laboratories and manufactured in our own factory—greatly extended in size during the past few months.

The Magnavox Power Amplifier has been designed for use especially in connection with the Magnavox Radio, and its use greatly increases your range and signal strength.

Every owner of a Magnavox Radio should also add the Power Amplifier Model C if he has not already done so.

R-2 Magnavox Radio with 18-inch Horn

FOR those who wish the utmost in amplifying power; for large audiences, dance halls, etc. Requires only .6 of an ampere for the field.

Price, \$85.00

Type R-3 Magnavox Radio with 14-inch Horn

THE same in principle and construction throughout as Type R-2, and is ideal for use in homes, offices, amateur stations, etc.

Price, \$45.00

Magnavox Power Amplifier Model C

INSURES getting the largest possible power input for the Magnavox Radio. Can be used with any "B" battery voltage which the power tube may require for best amplification.

AC-2-C, 2-Stage..... \$80.00

AC-3-C, 3-Stage..... 110.00

Magnavox Products may be had of good dealers everywhere.

Answer to Readers

CAN a small dry-cell tube be used as an amplifier. If so, will the regular amplifying-transformer function with it? Can such a tube be used in the Armstrong super circuit?—Joseph Mulacaha, Omaha, Neb.

This tube is called the aeriotron dry-cell vacuum tube and may be used as an audio-frequency amplifier; but it cannot be used with radio-frequency or the Armstrong super circuit. In employing this tube for audio-frequency amplification, the regular standard amplifying transformers may be employed. This tube will stand up under a plate voltage of 45 volts. Its filament operates on a single dry-cell, such as is used in an ordinary door-bell.

In a two-wire antenna, how far apart should wires be separated by the spreaders at each end. Are they joined at each end or only at the lead-in end? Can radio- or audio-transformers be put into a crystal circuit with satisfactory results?—Jacob Murs, Bayonne, N. J.

About two or three feet is the correct spacing for the wires. They should be joined only at the lead-in. Radio- or audio-frequency amplifying transformers are useless in a crystal circuit.

What is the best pair of phones to be had at a price not exceeding ten dollars? Can a pair of 2,000-ohm phones be used with any set?—Albert Murphy, Philadelphia.

It is impossible for this department to discuss the relative merit of the various competitive makes of radio instruments.

Is a loop aerial all right for a crystal set? Will it prevent interference? Which condenser is best for receiving, 43-plate or 23-plate?—Arthur Horn, Philadelphia.

The loop antenna will not give satisfactory results on a crystal set unless the set is located near a broadcasting station. Loop aerials, when used with vacuum tubes, have the marked advantage of eliminating interference. Either the 43-plate or the 23-plate condenser may be used, although the latter will permit of finer tuning. The 43-plate condenser has the greater capacity.

Will you advise me what to do with my variometer set? I cannot get any signals, only a lot of screeching and howling. Enclosed you will find my hook-up?—Anxious.

The only change that may be suggested is to place the rheostat in the positive side of the A battery and join both negatives of the A and B batteries to the return lead from the secondary of the vario-coupler. In order to make this change, all that is necessary is to simply change the connections of your storage battery, leaving the set wired as it is. If you have the set wired up, exactly, according to your diagram, with this one exception, there is no reason why you should not hear signals. Are you sure you have the positive terminal of the "B" battery jointed to the plate of the vacuum tube?

If a radio-frequency transformer is enclosed in a metal covering which is grounded, would it prevent induction received from the transformers of the set and the coils used?—Harry Starr, Duluth, Minnesota.

In a case where a radio-frequency transformer has an iron core, it should not be necessary to shield it in the manner you suggest. If an air-core transformer is employed then the various steps must either be very widely spaced or some shielding arrangement made. The shield, however, must

be perfect, or it will possess undesirable capacity effect.

Is the enclosed hook-up of a 2 vario-meter, 1 vario-coupler set correct? What would be the wave-length range and receiving range of such a set? Are the 23-plate or the 43-plate condensers better? Would it be all right to hook a loading coil in series with the antenna of such a set; or, is it necessary to load the secondary also? Can a 3step amplifier be later connected to the set?—Julius Hemmer, Albany, New York.

The hook-up is correct; but as you do not give us details as to the windings, we cannot tell you the wave-length range. However, such sets usually tune to about 600 or 800 meters with the average antenna. It is impossible to tell the receiving range of any outfit. The smaller the variable condenser, the more accurate the possible tuning; although, in your case, we would recommend a 43-plate condenser in the primary circuit and no condensers in the secondary circuit. You must load both primary and secondary simultaneously; but loading is not satisfactory with this type of set. An amplifier may be connected later to the phone terminals.

Where may I obtain a list of calls of the various stations?—Austin Foote, Tenafly, N. J.

Write the Government Printing Office, Washington, D. C., enclosing a money order for 15 cents.

I have a two-stage regenerative set with

His First Concert

(C. Photopress, N. Y.)

a hundred-foot aerial. I was receiving WOR wonderfully. By disconnecting the tuner and replacing it in its original position, previous signals were not so loud. What is the reason for this?—Grenville Moller, Tonawanda, N. Y.

This is the old story of fading. It is a condition which cannot be controlled. It generally happens when signals are loud. This paralyzes the tubes, making the signals weak. Shut' down the set, allowing the tubes to recover, and experiment again.

If U-V 201 bulbs are used on the super-regenerative set, what adjustments are required?—Joe Poli, Kew Gardens, N. Y.

If you use U-V 201 tubes in place of the 202 tubes, it will be necessary for you to cut down the necessary amount of plate voltage. In this event, we suggest that 80 volts be used on the plate circuit of the first two tubes, and 120 volts on the plate circuit of the second tube. No other change is necessary.

With reference to the Armstrong super-regenerative circuit, how many coils of wire are used on the vario-coupler primary for 360 meters? How many on the secondary of the coupler? How does the loop connect itself to the coupler?—Paul Remmeler, Poughkeepsie, N. Y.

Any standard vario-coupler with a wave length from 150 to 500 meters will answer the question. The only difference being that you will have to put twice as much wire on the secondary. The two leads from the loop aerial should be fixed to each end of the vario-coupler. The tuning of the loop is then obtained by means of varying the condenser, which is placed across the loop and the vario-coupler; and, also, if necessary, by placing the attaching clip on the lead at different points along the outside wire.

Is a loop aerial all right for a crystal set? Will it tend to prevent interference? Which condenser is best for receiving sets—the 43-plate or the 23-plate?—Kenneth Kiefer, Mineola, L. I.

The loop antenna will not give satisfactory results on a set employing the crystal, unless you are very close to a broadcasting station. The loop antenna will eliminate much of the interference. Either the 43-plate or the 23-plate may be used, although the latter will permit fine tuning when placed across secondary of vario-coupler. The 43-plate is used in series with antenna.

I wish to construct a crystal receiving set employing a double-slide tuning coil, a variable condenser in the aerial lead-in with a fixed phone-condenser. It is desirable that the coil be as short as possible, but long enough to insure the reception of 400 meters. Assuming a properly installed aerial, 100 feet long with a 30-foot lead-in, what should be the diameter of the coil and how long the winding? Would a coil wound on a solid wooden block be as efficient as one wound on the regulation cardboard tube? If so, would a coil wound on a flat wooden block of equal circumference be equally as efficient?—John Matheus, Huntington, N. Y.

Your coil should be about 2½ inches in diameter and wound for 3 inches of its length with No. 22 wire. A solid core is not as efficient as a hollow core, as solid cores cause dielectric losses. A coil is almost efficient when it is round and, therefore, a flat wooden block is much less efficient than a round one.

Is it possible to use a very small coil with a condenser to increase its wave length? Why is this not done more frequently?—George F. Rye, New Bedford, Mass.

In receiving work, it is advisable to have a preponderance of inductance, as a maximum of efficiency is obtained when the voltage is greatest; and the greatest voltage is obtained across a coil rather than across a condenser. Therefore, it is advisable to use as little capacity as possible.

MO, New Radio Craft

Test of New Radio-Equipped Naval "Spotting" Plane Made At Cleveland.

A NEW Naval "spotting" plane equipped with a recently perfected radiotelegraph set was tested officially before a board of Naval officers at Cleveland, Ohio, November 15. The plane is a three-seater, designed for observing and reporting to ships in action the fall of shells and their distance from the enemy ship or target. It is the first of several newly developed spotting planes designed for Naval work and was built by the Glenn Martin Company.

One of the most important features of the "MO," as the craft is designated, is its radio equipment, which is said to especially meet the requirements of instantaneous and constant communication by radiotelegraph between the spotters and the flagship, where the fleet gunnery officers and the admiral control the fire, or to individual ship's gunnery officers if the fire is controlled separately.

Only general information regarding the Navy's spotting radio sets is available, but it is known that the sets so designated are modern tube telegraph sets operating on continuous wave, and having excellent characteristics for range and reliability. They are especially rugged in their construction and guaranteed to "stand up" better than the ordinary radioplane sets. Power and range are withheld, but it is understood that they will transmit 300 or 400 miles. Satisfactory communication is assured, even though a great number of planes are sending messages at the same time.

The power is generated by a wind-driven generator with a self-regulatory fan giving constant revolutions at all air speeds, so as to furnish the tubes with a steady voltage.

Progress in Electricity

American RADIO Exposition

The Official Exposition for American Manufacturers

with the endorsement of the

NATIONAL RADIO CHAMBER of COMMERCE

and sanction of the Radio Apparatus Section of the

ASSOCIATED MANUFACTURERS of ELECTRICAL SUPPLIES

Grand Central Palace
New York

December 21st to 30th

(Sunday excepted but Christmas Day included)

This first really comprehensive Exposition to be staged in a manner worthy of a great industry includes such representative exhibitors as:

- Western Electric Company, Inc.
- Radio Corporation of America
- National Carbon Company
- C. Brandes, Inc.
- Sloper Radio Company
- General Insulate Company
- Executive Radio Council
- Coto-Coll Company
- Western Electrical Instrument Co.
- American Radio Relay League
- Stromberg-Carlson Mfg. Co.
- Holtzer-Cabot Company
- Clapp-Eastham Company
- Dubilier Condenser Company
- DeForest Radio Telephone & Telegraph Co.

All of the above and other leading manufacturers have contracted for space and many more are at present negotiating for representation. The opportunity to display Radio products to thousands of buyers during the holiday season is an unusual one. The exposition will be one of New York's big features in connection with National Radio Week.

Coming Events

The editors of RADIO WORLD will gladly publish news items of all contemplated radio shows and exhibitions. Keep us posted by mailing full information.

SECOND NATIONAL RADIO EXPOSITION, direction International Trade Exposition Co., Chicago, January 13 to 20, inclusive, 1923, George A. King, director of publicity, 417 South Dearborn Street, Chicago, Ill.

PERMANENT RADIO FAIR FOR BUYERS, Hotel Imperial, New York City. Open from September, 1922, to May, 1923.

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, December 21 to 31. Colwell & Korbell, Fisk Building, New York City, directors of publicity.

INTERNATIONAL RADIO SHOW, Madison Square Garden, New York City, November 20 to 25, inclusive. E. C. Buchigani, director of publicity.

SOUTHEASTERN RADIO EXPOSITION, Auditorium Armory, Atlanta, Georgia, December 4 to 9, inclusive. Co-operative Radio Sales Assn., 205 Peachtree St.

SECOND DISTRICT RADIO CONVENTION, Hotel Pennsylvania, New York City, March 1, 2, and 3, 1923.

A Loud-Speaker Crystal Set

THE Steinmetz Wireless Manufacturing Co., of Pittsburgh, claims to have perfected an amplifier for crystal receiving sets which possesses the added advantage of requiring no storage battery.

This amplifier may be used on any crystal set. It is sold in convenient units so that one, two, or three stages of amplification may be added when necessary. These units use a "peanut" tube requiring only a single dry-cell instead of the usual storage battery.

To insure against interruption in the operation due to cat's whisker not being on sensitive point, the manufacturer provides an ultrasensitive crystal which, he claims, makes interruption almost impossible.

Eisemann Magneto Line

THE Eisemann Magneto Corporation announces a line of radio parts designed to suit the most critical. Each part has points of originality that separate it from all other products now on the market. Ready for delivery are vario-couplers, variometers, variable condensers with verniers, audio-transformers, sockets, and phones, each made to the highest standards.

A feature of the panel parts is the concave bridge-dial which eliminates all protruding knobs, and acts as a shield. Switch points and levers are eliminated with the vario-coupler. All molded parts are of genuine bakelite highly polished.

This line may be had through Clark & Tilson, 1 East 42nd street, New York City, who are prepared to supply descriptive matter for each part. The prestige of the Eisemann Magneto Corporation is guarantee that its articles are the standard of quality.

Outcasts!

THE radio manufacturer of lesser magnitude who would succeed should advertise—after he has assured himself that he has a product worth advertising, says "The Mail," New York. The last two months of merchandising experience has shown that the buying public is insisting upon the products of the better known manufacturers. *The product without a name is rapidly becoming an outcast.* All of the big department stores are carrying only apparatus that has established itself in the mind of the public.

This is a very healthy indication. It shows that the radio industry is fast reaching rock bottom. It is actually starting to gather the prestige that it

deserves. In another six months' time, many of its ills and sores will be cured.

During the past few months, capital has flowed out of the radio field almost as fast as it flowed in last spring. That is also a good indication, for the get-rich-quick artists have been shown that radio is more than a match for their wits.

U. of I. Gets Busy

THE University of Illinois has opened its fall season with broadcasts on Monday and Thursday nights from 8.30 to 9.15. Its station, WRM, is operated by the electric engineering department.

New Firms and Corporations

(The firms and corporations mentioned in these columns can be reached by communicating with the attorneys, whose addresses are given whenever possible.)

Wilmac Electric Corp., Queens, \$5,000; J. J. McFarlane, Mr. Williams, A. Schichowsky. (Attorney, M. Friedberg, 116 Nassau St., New York.)

Fremont Radio Sales Co., Manhattan, \$5,000; E. and S. and H. Nagler. (Attorney, J. D. Nussbaum, 84 Rivington St., New York.)

Educational Radio Corp., Del., 3,000 shares common stock, no par value. (Representative, D. Freeman, 342 Madison Ave., New York.)

Let Radio World Test Your Goods

MANUFACTURERS, send a sample of your goods to our Technical Editor, Fred Charles Ehlert, 9006 Pleasant Street, Queens, Long Island, New York. It will be carefully tested. If your goods satisfy our experts, RADIO WORLD'S endorsement will be published in our merchandise department without charge or obligation of any kind on your part. When the radio purchaser sees a published test in RADIO WORLD with the seal accompanying this editorial attached, he will know that the product stands for perfection and has the guarantee of RADIO WORLD. RADIO WORLD is rendering a service through its testing department that is prompt, accurate and produces results. All goods will be returned to manufacturers, after testing, provided stamps are sent for that purpose.

Remember "This Is a Radio Christmas"

and that millions of dollars will be spent during the holiday time for radio gifts.

Be sure to get your share of this business by advertising in the issue of RADIO WORLD of December 9, which will be

RADIO WORLD'S CHRISTMAS NUMBER

Thru this medium you can reach thousands of readers, who are not only interested in radio themselves, and want new equipment, but who also will give presents to others whom they wish to make radio fans.

ADVERTISING RATES:

Regular advertising rates in force for RADIO WORLD'S HOLIDAY RADIO GIFT (CHRISTMAS) NUMBER, as follows: \$150 a page, \$5 an inch. Discount, 10% four times, 15% thirteen times.

Last form closes November 30, A. M.

Take advantage not only of RADIO WORLD'S circulation, but also its cash-thru-the-mail pulling power.

Be represented in RADIO WORLD'S Holiday Radio Gift Number, and reach the many thousands who actually want your goods and are ready and willing to pay for them.

Preferred Positions Must Be Booked Immediately.

Copy for run-of-paper position will be received up to November 30, A. M.

RADIO WORLD, 1493 Broadway, New York

My Emergency Radio Receiver at 2 AAR

By George Steier

2AAR, 584 East 139th Street, The Bronx, New York, N. Y.

In response to RADIO WORLD'S request for any interesting constructive work in radio that might have been perfected by its readers, Mr. George Steier, 584 East 139th street, The Bronx, New York, sends the following account of an emergency receiving set which, he claims, may be depended on in all sorts of weather.

George Steier

Mr. Steier's receiver employs a new circuit designed after careful research—a crystal detector mounted inside and adjusted by a set screw at the bottom. Its wave length is from 150 to 750 meters. The selective tuning is by means of a 15-point switch. The actual size of the receiver is 3 inches by 2 inches.

tance reception. As a broadcasting receiver, the results equal that of a one-bulb set. WGY, Schenectady, and a host of other stations at quite a distance are heard every night.

The set has had a more or less interesting career, having been adjudged the second best receiver for use by the New York City Police Department. In a pocket-receiver contest of over sixty entrants, this receiver was nosed out of first place by the small margin of five points. It was considered by the judges a most ingenious piece of radio work. The set is, also, very satisfactory for amateur reception. Government stations on 600 meters can be heard pounding in, five feet from the phones.

The pocket radio-receiving set invented by George Steier (shown at left) compared with a single head-phone (shown at right), and fully described in the accompanying article

HOW many times during a year are radio amateurs using tube sets, forced to give their phones or loud-speaker an involuntary rest due to a rundown battery. The writer, being no exception, found it annoying to shut down for a few days and determined that an emergency set that required no "juice" was the necessary thing. But, alas, no spare space was available for a rather cumbersome crystal set. The writer began a battle of wits with his radio knowledge, and, after some research work, designed the set shown in the accompanying photograph which requires the small space of 3 inches by 2 inches.

A number of pocket, or small, receiving sets have been described from time to time. I make no claim to first honors. However, most of these sets are of a freakish nature, more or less. My emergency set may be depended on during all sorts of trying weather conditions. The circuit employed is one of my own and was especially designed for long-dis-

Brooklyn Man Wins Code Honors

J. C. Smyth, 2 CKB, Declared World's Champion After Taking Three Contests.

JOSEPH C. SMYTH, 2 CKB, 269 Eighty-Sixth Street, Brooklyn, holds the World's radio championship. The title was awarded him at the New England Amateur Convention held at Boston.

Competing against Mr. Smyth were Theodore R. McElroy, former world's champion, and Walter Vetromile, both of Boston. There were three separate code contests: "jamming," cipher code, and straight press, the stipulation being that the contestant showing to best advantage in the three contests would be

(C. Sport-Commercial) Joseph C. Smyth at the "speed key"

awarded the silver cup and the title; Mr. Smyth won all three.

In the jamming contest two transmitters were sending simultaneously into the phones, and the contestants were required to ignore the signals from one transmitter, and copy the other, a rather difficult assignment. Mr. Smyth won this at a speed of thirty-five words per minute without error.

The cipher code consisted of ten-letter code words secretly prepared, and transmitted by a Wheatstone transmitter. This contest was won by Mr. Smyth who again made a perfect copy and broke the world's record for speed in cipher-code receiving by copying the difficult words at a speed of forty-four words per minute.

The straight-press contest presented the closest race of all, as both Smyth and McElroy made perfect copies at a speed of forty-five words per minute, and again at a speed of fifty words. However, at fifty-five words per minute McElroy made six errors, while Smyth made five, thereby winning the world's title in all three.

Free Radio Instruction at Mass. Inst. of Tech.

THE Massachusetts Institute of Technology, Cambridge, offers a free course in radio to extension students, this winter. The first care of this elementary course will be to give students an idea of what really constitutes radio and to supply the necessary theory for the intelligent handling of a receiving set. No previous knowledge of electricity is required. Classes are held at 7.30 p. m., in room 275 of Tech Building No. 10, on Tuesdays and Thursdays. M. T. Dow and E. L. Bowles, both of the Institute, are instructors.

Show Will Be Exclusively for Fans

THE Council of the Second Radio District has decided that the annual show to be held next year, (March 1, 2, and 3) at Hotel Pennsylvania tentatively, will be open exclusively for amateurs. This restriction has been made, it is said, because at the show held at the same hotel last year, the crowds were so large that radio amateurs were prevented from approaching the exhibition booths to see what manufacturers had to display.

FANS, AMATEURS, DEALERS, BROADCASTERS, MANUFACTURERS, AND THE GENERAL PUBLIC

Are Looking Forward to

NATIONAL RADIO WEEK

DECEMBER 23 TO 30, INCLUSIVE

All Interested in Radio Should Help to Make This Event a Smashing Success.

If you want to know more about it address:

NATIONAL RADIO WEEK EXECUTIVE COMMITTEE
J. ANDREW WHITE, Chairman

HIGH GRADE CABINET

LOUD SPEAKERS

Do not be deceived by our prices. **SPIROLAS** are not cheap instruments—they are a remarkable development made possible by the invention of the **SPIRAL** tone chamber (pat. pend.), which not only allows us to market a cabinet speaker of established high grade at an almost sensational price but gives many exclusive advantages over even the usual cabinet type, which is nothing but an ordinary horn enclosed in a cabinet—extreme compactness for a full-sized tone chamber and really complete elimination of metallic "horn" noises. **SPIROLAS** are made for music lovers who appreciate absolutely pure, natural tone.

We make a complete line—of equally high-class construction throughout, with fine hand-rubbed finishes. **ALL SPIROLAS ARE SOLD UNDER ABSOLUTE MONEY-BACK GUARANTEE—price immediately refunded if returned in ten days.**

SPIROLA CONCERT—complete with special powerful built-in unit and cord ready to hook up like phones, beautiful oak (Model CO) or mahogany (CM) finish **\$12.50**

SPIROLA DUPLEX—improved type for use with your headset, two complete in one, eliminating usual interference between phones, oak (DO) or mahogany (DM) finish, braided throat **\$4.85**

Set in black finish all over (DB) **\$3.85**
SPIROLA SIMPLEX—for use with Baldwin or other loud speaker unit, oak (SO) or mahogany (SM) finish, braided throat **\$4.85**

Set in Black finish all over (SB) **\$3.85**
At dealers or postpaid, carefully packed (C. O. D. if preferred).

IMPORTANT NOTICE:

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

New Broadcasting Map

THE Radio Section of the Department of Commerce has found it necessary to use a larger broadcasting map, the old one having become too small for practical use in locating the 564 broadcasting stations now in existence. The new map, which is 5 by 7 feet in size, is divided into radio districts, and each station is located in its approximate position.

The Difference Between Audio- and Radio-Frequency

WHAT is the distinction between "audio" and "radio" frequency amplification? ask Howard Allen Duncan in "The Globe," New York. And Mr. Duncan replies: The first is named "audio" frequency because it amplifies oscillations that vibrate within audible limits. This limit is usually reckoned to be between 16 and 20,000, this last being the upper limit for the human ear. For radio frequency, however, the oscillations may vibrate hundreds of thousands and even millions of times per second, and the detector must bring them down to audible limits, so that they will actuate the telephone receivers, or other recording devices connected in the circuit.

Radio- and audio-frequency amplifications are entirely distinctive, and they both fulfil different and separate functions. One cannot take the place of the other, and one may not produce the same results as the other.

Radio-frequency amplifiers should not be used to obtain loud signals, or when it is desired to have volume. This work will be better performed by the audio-frequency amplifier. However, when it is desired or necessary to amplify weak signals, so that they can be made to actuate the detector, the radio amplifier is the one used.

In distinction to the audio-frequency amplifier, which is hooked on after the detector in the receiving circuit, the radio-frequency amplifier comes first, and then is followed by the detector. This is an advantage, for it permits the use of any type of rectifier, and allows the addition of audio-frequency amplifiers after the detector, so that the amplified signals can be made still louder by its means.

Thus, radio-frequency amplification magnifies signals so that they are much stronger when they reach the detector. This has the same effect as though the transmitting station were moved much nearer the receiving set. Any number of amplifying radio frequency steps, or stages can be used in a receiving circuit. There is, of course, a practical limit, and that is considered to be about four stages, for beyond that point the operation of the set becomes so critical and unstable as to make it difficult to tune it and get good results.

Argentina Organizing in Radio

ARGENTINA has just organized a radio association in the City of Rosario, with forty members, according to a report from Consul Bonney, to the Department of Commerce. The organization intends to obtain board-of-trade quotations from Buenos Aires by Adolfo Elias, J. Torres, Lorenzo Aguerreberry, Alfredo Muzzio, C. J. Todman and G. O. Caesar are the organizing committee. Experimental receiving radio sets are made in Rosario by C. E. Smith, of Smith & Kirkwood, and sell for about \$38; but difficulty is anticipated due to the fact that the radio patents are controlled by a company in Buenos Aires and patent interference is anticipated.

Future of Electricity
 In Next Seven Years It Must Accomplish as Much as It Has in Its History

BETWEEN now and 1930, the electrical industry will be called upon to accomplish as much as it has already accomplished so far during its entire history, and between the years 1930 and 1937 it will have to do four times as much, declares Guy E. Tripp, chairman of the Westinghouse Electric and Manufacturing Company in an article on the "Future of the Electrical Industry" in the current issue of the "Magazine of Wall Street."

Until recently, the electrical industry, like most industries, says Mr. Tripp, developed haphazardly and grew by blindly following lines of least resistance. In its early days, no one could estimate its possibilities—or rather, those who did foresee the immense development that has actually taken place, were derided as visionaries. To-day, the chief factors governing electrical progress are known with a reasonable degree of accuracy; and provided that no radical industrial or economic changes take place during the next fifty years, the electrical industry will, during this period, in all probability develop along well defined lines.

One of the established facts is that the United States can use to advantage practically all of the electrical energy that can be generated within its borders. Everyone concedes the superiority of electricity for lighting; for driving industrial and mining machinery; for producing heat for industrial processes; for the manufacture of many chemical compounds, such as abrasives and fertilizers; for supplying power on the farm; for cooking, heating and operating a variety of labor-saving devices in the home; and for limitation need not worry the present generation, or the next. We have available in the United States about fifty million horsepower of water power, of which only about eight millions are now in use. It will be many years before all of this power is developed; and, when it is, it will be utilized in conjunction with huge steam plants that will produce power from about one pound of coal per kilowatt hour. Though our fuel supplies are undoubtedly diminishing, it will be centuries before they are exhausted at this economical rate; and by that time some of the newer forces, with which our physicians are busy, may be at our disposal.

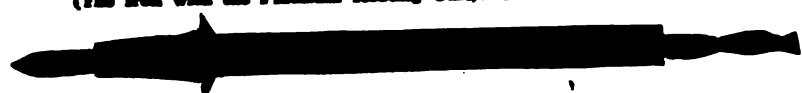

The real limitation to electrical development is set by finance. The nation's present annual income is figured at about seventy billion dollars, of which the average surplus available for permanent investment, after providing for the needs and pleasures of our people, is about ten per cent. From this surplus must come the funds for all permanent improvements of every kind—every addition to our railways, mines, factories, farms, homes and highways.

Broadcast Bill's Radiolays

By William E. Douglass

THANKSGIVIN' DAY at our house is a big event each year, when our folks get together, don't let nothin' interfere. There's me an' Min an' little Bill, an' Sister Jennie too, and my Aunt Soph from Goose Grease Creek an' also Uncle Lew. Then there's my brother Charley who works in a jewelry store down east in "Little Ol' New York." You know, he makes me sore the way he acts since he's been East with all his city tricks an' makin' fun of all of us—refers to all of us as "hicks." His wife, she ain't much better, puts on dog an' carries on, gets up about nine-thirty after all the work is done. Of course, there's Jim, our hired man, dressed in his Sunday best, with bran' new yaller button shoes an' fancy cross cut vest. Maw an' Paw live here with us; Maw helped Min with the dinner an' when them two start workin' they kin sure produce a winner. We had turkey, squash an' cranberries, spuds an' cabbage slaw, pickles an' homemade preserves, the best you ever saw. Maw mixed up some biscuits—Boy! they'd melt right in yer mouth, she says she learned to make 'em when she lived away down South. But when it comes dessert time, there's where my wife takes the prize. There aint no one kin beat her makin' mince and pun-kin pies. The dinner started off with grace then each one had to tell what he

had to be thankful fer besides just bein' well. Dad said that he wuz thankful he could have his children here so they could be together fer at least one day each year. Charley's wife said she was glad she had her "darling pet,"—my Dad just give her one good look, she aint fergot it yet. Aunt Soph and Min an' Jennie, Little Bill an' all the rest gave thanks fer all the favors with which each one had been blessed. An' when it came to my turn to speak I guess most of them thought I'd say how thankful I wuz for the crops this year has brought, but that's right where I fooled them fer I'm thankful I know because a feller called on me about a year ago an' handed me some happiness I never will ferget. You've guessed it right—for that wuz when I bought my wireless set. (Copyright 1922, Westinghouse Electric & Manufacturing Company.)

"Radio Golf!" Next?

SILENT periods between broadcast programs have been instituted in Boston by Radio Inspector C. C. Kolster, so that fans may have a chance of tuning in long-distance stations without experiencing local interference. They can now play "radio golf," as it is called, when trying to receive distant stations without sitting up late at night.

Big Show Getting in Shape

Space for American Radio Exposition Being Taken Up by Leading Firms

THAT the American Radio Exposition, to be held in Grand Central Palace, New York City, December 21 to 30, inclusive, promises to be a success, is emphasized by the large companies exhibiting that have pledged their co-operation. The exposition has the support of the National Radio Chamber of Commerce and, also, is sanctioned by the Radio Apparatus Section of the Associated Manufacturers of Electrical Supplies.

It will be one of New York's big features. The slogan, "This is a Radio Christmas," has caught on. Many firms connected with the wholesale and retail ends of the business feel that the combined movement will result in a remarkable trade stimulus.

The exposition to be held in the Palace will be the first of a series of annual shows national in scope and analogous to such expositions as the annual Automobile Show, Motor Boat Show, Silk Show, and the Flower Show. All of these expositions have been a big incentive to buyers in their respective industries. Dealers from many parts of the country visit them, as well as the consumer public.

The show at the Palace is primarily a manufacturers' official exhibit, but dealers and jobbers representing manufacturers will also display. Special morning hours will be arranged for dealers in the morning. During these periods the public will not be admitted.

With the exposition enjoying the support of such exhibitors as the Radio Corporation of America, De Forest Telephone & Telegraph Company, Western Electric Company, National Carbon Company and others, the attractiveness of the various exhibits is assured.

Frank Hitchcock, former post-master general, is head of the American Exposition Company. Walter Gordon Clark is vice-president, and Harold Bolster, secretary and treasurer. The offices are at 120 Broadway, New York City, where L. S. Byers, executive secretary, is in charge.

Some of the prominent manufacturing corporations that have engaged space at the exposition include:

Western Electric Company, Radio Corporation of America, C. Brandes, Inc., National Carbon Company, Novo Battery Company, Sleeper Radio Company, General Insulate Company, Sound Wave Corporation, Pacent Electric Company, Stromberg-Carlson Manufacturing Company, Holtzer-Cabot Company, National Airphone Corporation, Clapp-Eastham Company, Hutchison Radio Company, Henry Hyman & Co., De Forest Radio, Dubilier Condenser Co., Inc., Coto Coil Company, A. H. Grebe & Co., Weston Electrical Instrument Company, American Radio Relay League, Executive Radio Council, Burgess Battery Co.

To Germany on Telefunken Sale

ALFRID FRANKENTHALER, a lawyer of 120 Broadway, took passage on the Cunarder "Aquitania" for a hurried trip to the Continent to represent many Germans whose property here was seized by the Alien Property Custodian. He said that the sale of the Telefunken wireless concern by the Custodian "for a nominal consideration," had led him to urge upon Washington an amicable adjustment for his clients and that satisfactory progress was being made. He believed the Winslow resolution providing for the return by the United States to Germans of sums up to \$10,000 would soon become law.

Radio in a Talking-Movie

THE General Electric Company through its radio broadcasting station, WGY, Schenectady, New York, recently told thousands of people listening to the program that a new device, other than the phonograph, was being used to "talk" into the radio transmitter. But no particulars were given of the device used.

Then came Thomas A. Edison to the Schenectady plant. He had not been there in twenty-five years and there was much to show him. Being the inventor of the first device to record speech so that it could be reproduced, he was intensely interested in this new machine.

So he was taken to C. A. Hoxie's experimental room in the General Laboratory, where the pallo-photo-phone, invented by Mr. Hoxie, was shown and demonstrated. Here a film, which looked in every respect like a motion-picture film, was run through a machine with a powerful light thrown against it—just as in the motion-picture projection machine—and from a loud-speaker and head phones the voice was heard, full and strong, with all its variations of tone, all its stops and hesitations, all its vital quality inherent in its reproduction.

Edison marveled, "What next?" he asked.

There are two great possibilities to this machine. First it makes possible the

talking movie, for on a film of the normal width can be the picture and voice, absolutely synchronized. The picture and voice must work together at all times for both are a part of the same film. Secondly, it means a boon to radio broadcasting studios. From a central studio, say in New York City where most of the great artists are located, the artist can sing, play some instruments or talk, into this machine which produces the film. Copies of the film

L. T. Robinson, engineer in charge of the General Engineering Laboratory in which this machine was designed, explains its operation:

"This is a device for the purpose of recording sounds upon a photographic film so that the sound may afterwards be reproduced in ordinary telephones or loud-speakers. The record is made by causing the sound waves to produce vibrations on an exceedingly minute and very delicate mirror. A beam of light reflected by this mirror strikes a photographic film which is kept in continuous motion. The film, when developed, shows a band of white with delicate markings on the edges which correspond to the sound which has been reproduced. On account of the exceedingly small size of the mirror, its low inertia, it is possible, by this means, to produce a sound record which includes the very delicate 'overtones' which give quality to speech and musical sounds. This has not been so successfully accomplished by any other method of recording sound waves.

"The reproduction of the sound from the film is accomplished by moving the film in front of an exceedingly delicate electrical device which produces an electromotive force which varies with the amount of light which falls upon it. In the past, attempts have been made to produce these results by means of selenium cells; but a selenium cell, though it responds to the changes in the amount of light which it receives, does not respond with sufficient promptness to produce good results. There is a sluggishness in the response which seriously interferes with the quality of sound which is produced.

"By an ingenious combination of vacuum tubes, there has been produced an apparatus which responds to variations in the light falling on it with a speed of light itself, or with the speed of propagation of wireless waves into space. Therefore, when this film is moved continuously in front of such a device, the device produces an electric current which corresponds very accurately to the original sound wave. This electric current may be used to actuate a telephone or loud-speaker. It has been used at the General Electric radio broadcasting station. The voice of the announcer was recorded on a phonographic film and sent out with such accuracy that it was impossible to distinguish it from the voice as directly transmitted from the station."

THIS IS the "SUNECO" TUBE ADAPTER

Eliminates the Storage Battery

The "Suneco" Adapter allows the use of the Aeriotron WD-11 dry cell vacuum tube in any standard socket.

- Minimum dielectric loss.
- Minimum induction effects.
- No soldering to corrode.

Big Tubes for Trans-Atlantic Radio

Messages Flashed from New York to Nauen, Germany, at the Rate of Fifty Words a Minute

POWERFUL electron-tubes developed in the research laboratory of the General Electric Company and applied to wireless telegraphy by G-E engineers working in cooperation with the engineering staff of the Radio Corporation of America have successfully bridged the Atlantic Ocean. On October 14, for a period of sixteen hours, the regular commercial traffic of the Radio Corporation was handled by a tube set between the Broad Street transmitting office of the Radio Corporation, New York, and Nauen, Germany. The tubes replaced the alternator, and traffic was handled so efficiently that the operators at the German station were not aware that they were participating in a revolutionary and epoch-making change in radio transmission.

A week later, Saturday, October 21, a second demonstration of tube transmission was made for E. W. Rice, jr., honorary chairman of the board of directors of the General Electric Company, and A. G. Davis, vice president. In this test, traffic was handled for a period of ten hours between this country and the Canarvon station, Wales. The receiving operators knew that tubes were being used. Messages were sent at the rate of fifty words a minute.

The set installed at Radio Central, Long Island, consists of three 50-kilowatt, 15,000 volt, water-cooled, metal vacuum-tubes, known in the engineering world as "kenetrons," and used as rectifiers and six 15,000 volt, 20-kilowatt, water-cooled metal pliotrons used as oscillators. For the demonstration with the tube set, a mile-and-a-half long antennae suspended from six towers, 420 feet high, was used.

The 20-kilowatt, water-cooled tubes are similar to those shown Senator Marconi on his visit to Schenectady. The tubes were developed by W. C. White and H. J. Nolte of the research laboratory and are constructed on the principles discovered by Dr. Irving Langmuir. Both Mr. White and Mr. Nolte worked with W. R. G. Baker, of the radio engineering department of the General Electric Company, in the installation of the tube set at Radio Central. With Mr. Baker, who had charge of the work for the General Electric Company, were Irvn Weir and August Schmidt, Jr., and C. W. Hansel, representative of the Radio Corporation of America.

It is not expected that the tubes will immediately supersede the alternators but the General Electric Company has convincingly proved that it is possible to build a tube equipment that will handle commercial traffic efficiently and economically. It is further claimed for the tubes that high-speed transmission may be easily obtained. The tubes may be run in parallel with the alternators, or separately.

This is not the first time that transatlantic wireless telegraph has been accomplished but on previous occasions the British used fifty-two tubes.

Transatlantic wireless telephony is now believed a matter of a very short time as the tubes are especially efficient for this system of communication.

Fifty-two issues for \$6.00. Sub. Department, Radio World, 1493 Broadway, N. Y. C.

Tropical Radio Company Gets Miami Naval Station

THE lease of the Naval Radio Station at Miami Beach, Florida, was awarded to the Tropical Radio Company of Boston, the highest bidder in the recent call for bids. This company, which is connected with the United Fruit Company, offered to take the station for eighteen months at an annual rental of \$3,600, with permission to extend the lease an additional year. The Radio Corporation of America, and Cutting & Washington of New York, also filed bids.

According to the terms of the lease, the Tropical Radio Company must replace the old rotary-spark set with modern equipment which will reduce the objectional noise to a minimum.

With the enactment of necessary legislation, it is understood that the Navy will ultimately offer the station for sale.

Radio Aids Einstein Tests

SPECIAL radio time-signals sent from SNSS, Annapolis, for the benefit of scientists in the Indian Ocean working on a test of the Einstein theory of relativity during the recent solar eclipse, were nearly twice as audible as those of a commercial station, the United States Navy has been advised. At least their time signals reached Paris satisfactorily. A radio station there reports that a comparison of the time signals sent out by the Navy with those transmitted from Rocky Point, Long Island, showed that the audibility of the Navy signals was 158.3 compared with 87.5 for Rocky Point on the audibility scale. Reports from Australia and the Indian Ocean have not yet been received. Naval signals were sent out on 17,145 meters and those of the commercial station on 19,000.

Static in the Tropics

Only a Radio Operator Who Has Worked There Can Fully Appreciate It

EVEN during the winter months static is very noticeable," says Charles A. Reberger, chief radio operator of the steamer "Atlantic," in "The Morning News," Dallas, Texas. "All day long it is a continuous roaring, grinding and crashing in the receivers. During the

hours of the night it is worse—far worse. Nine times out of ten the crashes will entirely blot out all signals.

"It is very difficult to work through heavy static. Let me give you an idea. One evening we attempted to establish communication with a station in the Canal Zone, which was about two hundred miles away from us, and failed. It was absolutely impossible to even hear his signals, due to the heavy atmospheric conditions. A vessel only ninety miles north of us could not read our signals, although we were then getting twelve amperes radiation and had a fine, clear musical spark. Radio engineers claim a musical spark is easily read through static interference.

"A few nights later, I had the pleasure of listening to Swan Island working a United States fruit liner. After this station had sent each letter twenty times, the vessel informed him that it could not distinguish his characters. Only an hour before he had forwarded his 'TR' to Swan Island and was no more than two hundred miles south of this land station.

"If one should 'listen in' during one of those ugly tropical thunderstorms I guarantee you would think you were at the battle of Liège or in a boiler factory."

Attention, Newsdealers

You should keep a good supply of back numbers of RADIO WORLD on hand all the time. It has been the experience of many dealers that a purchaser of RADIO WORLD for the first time will almost immediately want the back numbers, some of which are already out of print and some of which are difficult to get. **THE PUBLISHER WILL FURNISH BACK NUMBERS TO DEALERS DIRECT OR THROUGH THE AMERICAN NEWS CO. AND ITS BRANCHES.** Dealers should hold their unsold copies for a reasonable length of time. RADIO WORLD of October 28 contained a full page of contents of back numbers to that date. 15 cents per copy; any seven numbers for \$1.00. RADIO WORLD, 1493 Broadway, New York.

That Armstrong Circuit

So much interest has been displayed in the special article, "TESTED INVENTION OF MAJOR ARMSTRONG AMPLIFIES SET 100,000 TIMES," by John Kent, that appeared in RADIO WORLD No. 13, dated June 24, 1922, the publisher decided to put aside a number of copies for those who were not able to get this issue when published. Copies will be sent, postpaid, on receipt of 15c, or send in your subscription, \$6.00, for one year (52 issues), \$3.00 six months, or \$1.50 three months, and subscription will be started with the issue containing the article about Major Armstrong's Amplifier.—RADIO WORLD, 1493 Broadway.

HUTCHISON

The Final Word in Radio Apparatus

TYPE SK

This Complete Receiver

is simpler to operate, more efficient, more selective, less fussy than any we have ever seen. Embodies the Armstrong regenerative circuit, and many modern improvements found only in the highest grade instruments. Designed for the expert, but so simple that it can be handled easily by the novice.

Every detail of workmanship and finish is of the very highest grade. There is nothing finer at any price. Well known radio engineers have tested it

thoroughly, and marvel at its simplicity and efficiency.

The Type SK is a complete regenerative tuner, with detector and two stage audio frequency amplifier. Its output goes direct to phones or will operate any good loud speaker. Being designed for the usual broadcasting wave lengths (150 to 450 meters) it is very highly selective in this complete range, and delivers a clear, pure signal, remarkably free from the usual distortion or tube noises.

Offered only by leading retailers. If your dealer is not supplied, write us direct, mentioning his name.

Hutchison Radio Company

Canadian Pacific Building

342 Madison Avenue, New York

To the Trade:

The discriminating purchaser instantly recognizes the Type SK as an exceptionally fine instrument. Dealers handling it usually select it for their own store demonstrator. Jobbers and Retailers find it a ready seller, and their customers report unusual satisfaction. Our terms give the purchaser exceptional value and also provide a fair profit for the trade. Write or wire for particulars.

RADIO WORLD

(Trade Mark)

ILLUSTRATED. WEEKLY

Miniature Radio Transmitter Fits Kodak Case

AN unusually interesting miniature transmitter is shown in the accompanying photograph. It was built and designed by Sterling G. Sears, and will give satisfactory service to the novice who is satisfied with comparatively short range. The set shown has a transmitting range of about three-quarters of a mile and a receiving range of about seventy-five miles. The apparatus is mounted so that it fits into the interior of a kodak-camera case. Note the neat appearance and arrangement of the coils, batteries, and the miniature vacuum-tube. For B batteries, in this particular case, flashlight batteries are used exclusively. The reason for this is that they take up little space and afford the necessary plate voltages for the vacuum tube. The filament may be lit by the ordinary battery. As a means of inductance a spider-web coil is used as a means of controlling the wave length. The taps are shown on the front of the panel. The rheostat, with the miniature vacuum tube, is also shown. At the rear of this is the spider-web inductance coil with its taps, while the grid leak and condenser are mounted on the center coil. The batteries are at the extreme back of panel. The wiring is extremely simple. With a limited knowledge of radio, the operator should find this set efficient. It is a practical transmitter and may also be used as a receiver.

MANUFACTURERS' RADIO ASSOCIATION

90 East Kinney St. Newark, N. J.

How Dr. Lee de Forest's Photofilm Works

THE process is outlined in general terms as follows in a letter by Mr. de Forest to his representative in New York:

- "Taking the picture:
 - "1. Sound waves (voice of the actor) translated into electrical waves.
 - "2. Electrical waves translated into light waves.
 - "3. Light waves recorded on the edge of the film.
- "Reproducing the picture:
 - "1. Light waves translated back into electrical waves.
 - "2. Electrical waves translated back into sound waves.
 - "3. Sound waves amplified with loudspeakers placed near the screen for the audience."

The stumbling block which has impeded other efforts to perfect the talking film has been the difficulty in exactly synchronizing the voice and the picture. This is important, since sound travels at 1,090 feet a second and light at 186,000 miles a second. Unless the word and action correspond exactly in time, as rendered by the talking-picture machine, the effect is spoiled. With the picture and the sound-wave on the same film, the time unity is preserved to the thousandth part of a second.

Canadian Radio Directory

CANADA published its first issue of the "Official List of Radio Stations in Canada." This list, which was compiled through the efforts of Commander C. P. Edwards, director of the radiotelegraph service under the Department of Marine and Fisheries, contains a complete roll of every amateur, commercial, military, and broadcasting station in the Dominion, and is corrected to August 1, 1922.

K. of C. Leads in Radio Instruction for Veterans of World War

(Both photos C. Kadel & Herbert)

Instructing a World War veteran in one of the radio schools of the K. of C., station 2AZK.

THE Knights of Columbus are conducting radio schools for the purpose of instructing veterans of the World War. Already nearly 20,000 veterans are receiving instruction in these schools. The large photograph on this page shows Instructor Thomas A. Berinati, at the left. He is instructing Ernest Vehstedt, a hero of the Argonne, in the workings of a half-kilowatt spark-gap transmitter. The spark-gap is the heart of the transmitter, and in this case, this particular gap makes it possible to secure what is termed a "pure, sharp wave." It is of the utmost importance that the student be familiar with the "how and why" of this gap, as it is vital when a man is taking examinations

How to solder a Marconi 106-B receiver.

for a governmental radio license.

To the left of Mr. Berinati is the receiving instrument with its necessary array of vacuum tubes for high amplification. All of these instruments are of vital importance to the student who expects to be an expert operator.

The small photograph shows the rear of a receiver of the Marconi 106-B type of tuner. This tuner has for its inductance and coupling the loose coupler as shown in the picture. A wire is being soldered by Mr. Berinati.

Once the student receives a license, he has an opportunity to travel, and, if he is alert and makes the most of his eyes, camera, and notebook, he may gather knowledge that will broaden his vision on life.

Getting Results Out of Your Receiver

By Charles H. Plath

Schematic diagram of a slide tuning coil. By sliding the two sliders on the coil inductance the wave-length is changed. Drawn by Charles H. Plath.

WHY is it necessary to have an outdoor aerial in order that a radiophone concert may be received? This is a question that is being asked frequently, particularly in view of the development of Armstrong superregeneration, radio-frequency amplification and other systems, which will function provided the loop aerial is applied to them. This loop aerial does away with the outdoor aerial and makes it possible for most anyone to hear the broadcast.

The answer to the question is important, because the success of the receiver absolutely depends on the aerial.

In order to illustrate the operation of an aerial, it is, perhaps, best to take the hydraulic analogy that has been developed by radio engineers as a means of describing an aerial. In reality, it must be understood that the ground and aerial act as a condenser—the aerial being one plate, the other being the ground. The tuner which, after all, is a variable inductance, is merely an arrangement that will permit one to increase the length of the aerial itself.

If one looks upon the aerial circuit as a large trough of water he will understand its functioning a little more clearly. Only recently articles have appeared regarding the aerial problem; but I am assured that there are still many who would like a simple picture of just how it takes its action.

If we picture a water trough and place a paddle wheel in it, we can then see the action or wave motion.

If we commence a steady disturbance in this trough by aid of the water-wheel, the water will be set into wave motion and will oscillate between the two ends of the trough according to the length of the trough; in other words, the natural frequency of the trough.

If this paddle is moved back and forth at a correct rate of speed equal to the natural period of the trough it will set up waves of maximum height which, in time, will pour over the sides of the tub. If, however, the rate of movement is too fast or too slow, the maximum wave-motion will not be attained. If we study the wave motion in the trough we will find that the maximum height of the wave is reached at either end of the trough, and that, as the water flows back and forth in an oscillatory manner, the greatest height is reached at each end of the trough.

In our aerial circuit this action is reproduced when the incoming wave sets up an oscillatory current in the aerial circuit. It will be found that the highest voltage is at either end of the aerial wire, and it is necessary therefore, that these two ends be thoroughly and completely insulated in order to prevent losses.

Now, we have exactly the same condition in the aerial circuit as we have described in the trough. If the incoming wave-length is too small it will not set up an oscillatory current in the aerial circuit. If it is too large, the same results will be obtained.

With the incoming wave close to the natural frequency of the aerial, we can make up for any small difference by means of an inductance that is connected in series to it. It is for this reason, therefore, that it is necessary to have a well-constructed aerial, free and clear of all objects where the ordinary normal circuit is used in order to get best results.

Radio Crop Service

A WORLD radio-crop service has been established by the United States Department of Agriculture. The Department has representatives in many important European cities, who send reports of crop conditions to Washington. The information is then broadcast over the United States. A recent message from the Berlin representative was received in Washington and relayed throughout the country in less than five minutes from the time the news left Germany.

Schematic diagram of a variometer which gives continuous variation of inductance. The secondary variable condenser is necessary for good results. Drawn by Charles H. Plath.

The inductance in the circuit will enable the amateur to increase the range of his set so far as the wave length is concerned, which is equivalent to varying the trough in the analogy. The addition of a condenser in series with the aerial will have a tendency to reduce the wave-length range of the receiver within certain limits.

The condenser in series with the aerial can be used for more flexible tuning purposes in the aerial. There is a very important point, however, that should be taken into consideration in conjunction with a series condenser in the antenna. In the first place, it is a fundamental fact in electricity that condensers placed in series with each other reduce the total capacity of the circuit and that is exactly just what happens when you place the tuning condenser in series with the aerial, because the latter is also a condenser.

In this connection, there is a very peculiar situation; if the detector circuit is connected to the aerial circuit in such a way that this condenser is included, a great stress will be placed on the detector. Consequently the efficiency of the receiver will be materially reduced.

It is necessary to connect the detector circuit around the aerial tuning-inductance only. Whether this aerial tuning-inductance consists of a straight tuning coil, a honeycomb coil, or any other form of coil does not make any difference. The detector circuit should be connected around it in such a way that the series condenser in the aerial is not included.

Sharp Tuning Will Help to Eliminate Interference

By Arthur O. Curtis

MANY sets made are almost impossible to tune sharply; but whatever sort of an outfit you have, an understanding of its tuning qualities will bring better results both in reduction of interference and signal strength. Interference is one of the greatest studies in the science of radio. With a crystal set using a single-slide tuner as the sole method of tuning, there is no choice in adjusting. Simply move the slider until the greatest sound is obtained. Interference from other stations may have to be tolerated. With this set, it may be impossible to prevent it due to the fact that a direct-coupler receiver is used.

A two-slide tuning coil offers a greater latitude of adjustment and, therefore, greater selectivity. It acts somewhat in the manner of a two-circuit, or loose-coupler receiver, with close coupling. The aerial slider should first be adjusted until signals are heard. The movement should be in the activity of the active end of the coil, or the end connected to the ground. When signals are heard, move the other slider until they are brought in loudest.

The loose-coupler set, which is the inductive type receiver, is the most efficient type for use with a crystal detector. In tuning such a set use close coupling—that is, have the secondary coil inside the primary coil. Set the secondary coil at some rather low value of inductance and adjust the primary by means of slider, or switch. The circuits are brought into resonance after the signals are heard by adjusting the secondary switch. Louder signals may be obtained sometimes by readjusting the primary. Interfering signals may be reduced by lessening the degree of coupling. For short-wave sets using vacuum tubes as detec-

The schematic diagram (above) shows a tuning coil with a variable condenser across the secondary. This makes the tuning sharp and helps to keep down interference from other stations. This tuning coil is of the single-circuit type. The schematic diagram (below) shows the inductive type of coupler. It has a primary and secondary. Again the variable condenser which is of .0025 mfd. capacity, helps to eliminate interference. This is known as a vario-coupler and is far more advantageous in radio work than the tuning coil. Drawn by Arthur O. Curtis.

tors, the regenerative hook-up has proved the best. The tuning elements in such a circuit consist of a vario-coupler, a grid variometer, a plate variometer and, sometimes, a series variable-condenser in the aerial circuit.

Tight coupling should be used in this vario-coupler. Adjust the primary switch; next, rotate the knob on the grid variometer until a howl or squeal is heard. Another squeal will be heard just past this point. Between these two points will be found a point of resonance at which the incoming signals will be heard. The plate variometer should next be adjusted until signals are loudest. It will be found that coupling variation will make a slight difference in the tuning, or in the strength, of signals.

It will be seen that the loose coupler has its limitations but it is far better than the tuning coil. It is more selective. It has two coils. It is of the inductive-type receiver—that is, one may select the station he wants among others that are transmitting at the same time. It is easier to receive with a loose coupler as it acts as a filter which passes the signals that are tuned in and rejects the undesired signals. This is true to a certain point, for it is not always that a very pure wave comes from a transmitting station.

If the transmitting station is very near the receiving station, it also will be hard to tune out. Thus it will be seen that the loose coupler is much more advantageous than the tuning coil.

The loose coupler probably is the most common tuning device used with a crystal detector. The lower diagram is a simple crystal detector, utilizing a loose coupler, also a fixed condenser across the head phones.

Nine More Broadcasters

Gimbel Brothers, Philadelphia, Licensed to Carry on 400 Meters

THE following Limited Commercial or Broadcasting Stations issued by the Department of Commerce, for the week ending November 17, carry on 360 meters:

KFAV—Abbot-Kinney Co., Venice, Calif.

WPAM—Awerbach & Guettel, Topeka, Kans.

WHAL—"Capitol News," Lansing, Mich.

WLAT—Radio and Specialty Co., Burlington, Iowa.

KFFA—Dr. R. C. Shelton, San Diego, Calif.

WNAY—Shipowners Radio Service, Baltimore, Md.

WPAD—Wieboldt & Co., Chicago, Ill. Two new Limited Commercial Class-B Stations on 400 meters are:

WIP—Gimbel Brothers, Philadelphia.

KHJ—Times Mirror Co., Los Angeles.

Belgium's Rulers Become Radio Fans

THE king and queen of the Belgians have become radio fans. According to recent dispatches they listened in to a test concert of the Maline Cathedral chimes, broadcast from the tower by radio.

The suggestion of broadcasting by radio

the carillon of Maline Cathedral, the seat of His Eminence, Cardinal Mercier, resulted directly from the successful broadcasting of chime music, on April 27 last, by WGY, radio broadcasting station of the General Electric Company. On that date, the McKim Memorial bells, now in the lofty tower of Epiphany Church, Washington, D. C., were played in the Old Meneely Bell Foundry at Water-vliet, New York. The foundry was connected to the transmitting equipment, sixteen miles away, by a telephone line. Colonel William Gorham Rice, of Albany, an international authority on carillon, heard of the success of the WGY concert. Since the World War, Colonel Rice has been devoting himself to the rebuilding of war-torn Belgium.

Inventors! Here Are Some Things Sorely Needed in Radio

By C. White, Consulting Engineer

THERE are, perhaps, thousands of radio amateurs and novices with practical ideas concerning radio improvements that, probably would net them modest fortunes if they had the courage to get behind their ideas and give them the necessary scientific backing. That a man is not a technical expert in no way renders him disqualified to perfect a new radio idea; in fact, many inventions come from men who had very little technical training prior to their conception of the lucky idea. If an amateur does not possess the right amount of scientific skill to perfect an invention, he should either take steps to acquire that skill or hire someone with the skill to supply the information and help him over the rough spots. I have personally known of many practical inventions along scientific lines that have proved profitable for the men who had sufficient foresight to seek the right kind of aid.

Radio as a field for inventions is exceedingly fertile, and the wise amateur is the one who fully realizes this and carefully sets his mind to work to accomplish some greatly desired improvement. Consider the radio receiver. We know that the art of transmission is far in advance of the art of reception, mainly because we have spent more time for the development and research of more powerful methods of sending; yet the receiver has been given very little attention until recently. The fact that radio reception has long been neglected is quite obvious when one stops to consider that some deep-sea vessels are still using the old magnetic type of detector, which is much inferior to the ordinary crystal that many novices have in their small sets. Another proof that reception has been neglected is the fact the radio-frequency had to wait so long in the experimental stage before completion; and, in some respects, it is still in that stage. If we resort to the tuned plate-circuit for radio-frequency amplification the tuning of the circuit becomes too critical for an ordinary case of adjustment and manipulation, while it is next to impossible to keep tuned if more than one stage is used. Then, again, if we employ many of the transformers for radio-frequency amplification, we cover the desired increase in range, but the band of

wave-lengths amplified greatly cuts down the desired selectivity which is quite paramount for long-distance work. There is, no doubt, some compromise between the two which will give perfectly satisfactory results and still give us selective amplification; so it is up to radio fans to find that combination and have it duly developed. It can be done, and if some one will only take the time to think up a possible scheme and then try it out with the aid of some reliable manufacturer, or technician, reward for his efforts will follow.

We need better types of tuning coils—coils that are relatively free from distributed capacity and have a very low effective resistance at radio-frequencies. In a recent test of some coils used in radio work, I actually found them not only to be extremely high in resistance loss but also extremely high in effective or distributed capacity. Now, since distributed capacity is a variable with frequency, it was actually found at high frequencies that the condensive action of the coil was greater than the inductive. This meant that the coil was nothing more than a condenser from the electrical standpoint. While it is true that the spider-web, and the honeycomb types of inductance are marked developments in the right direction, I think that there remains an ample field for further progress along that line. Specially stranded wire has aided to a certain extent,

to cut down high-frequency skin-effect, but, as we all know, there is still more room for improvement. We are just beginning to realize what may be done. In fact, the foremost technicians and radio-research engineers are so swamped with prospects of development along so many lines that they are forced to set aside many promising ideas that need careful consideration.

In the field of the short-wave, Mr. Marconi has asserted that we have entirely neglected the vast possibilities to be obtained from carefully planned study along this line. It hardly seems possible that we should plug away so many years on the development of the long wave for transmission of radio signals and completely—and for no good reason—ignore the realm of the short wave. Perhaps millions of dollars have been spent in the development of high-frequency alternators and different types of Poulsen arcs for generating long-wave undamped signals; yet the development of short waves has been generally overlooked. Amateur C-W stations have proved that with relatively small amounts of power they can send signals further than some commercial stations using many times as much power. I personally know of one amateur station, situated in New England, that has been heard at rather frequent intervals in Honolulu and England. This station uses only four 50-watt tubes. The amateur transatlantic tests that are to be held this month will show us how short-wave signals will carry with a relatively small amount of power.

I have given only a few suggestions of the needs in radio, but there are many more that are just as much needed as those I have outlined. For instance, there is still wanting, a simple yet effective means of filtering out static interference. Inventions for increasing the selectivity of a receiver are favorable from the scientific point of view. Methods of obtaining distortionless detection and amplification of radiophone signals are badly needed. Thousands of design improvements in every phase of radio-apparatus construction are awaiting solution. If you have an idea don't let it go to waste simply because you have not the means available for skilful perfection and development.

The Grid Condenser and Leak

THE sensitiveness of a receiver is greatly increased by inserting a grid condenser and leak in the grid circuit in series with the grid of the tube. This usually consists of a small fixed condenser of about .00025 mfd., in shunt, or parallel, with the grid leak of about .5 megohms (500,000 ohms), though these values are not fixed value but should be adapted to the correct tube used. Simply defined, the grid leak is an instrument that will allow extremely small currents to "trickle" through. Grid leaks are generally supplied in complete units and are frequently encased in glass tubes for protection.

Radio Facts

IRON, steel, or galvanized wire is never used for aerials, because they have too low a resistance. Copper is generally used, simply because it is a better conductor of electricity than any of the other conductors mentioned.

* * *

If your ground is poor, signals from broadcasting stations cannot be expected to be heard at any great signal strength. Signals may be so weak at times that it will be impossible to hear anything at all. This is very discouraging. When making a ground connection, don't wrap the wire around the pipe or radiator.

* * *

Body or hand capacity effects may be eliminated if the back of the panel is shielded with thin copper and grounded to the ground binding-post. Copper sheeting may be placed also between the various variometers, care being taken that the sheeting does not come in contact with any of the wires. The variometers should be spaced about 4 inches apart.

* * *

Electrically, the cage antenna handles a given amount of energy with less rise in voltage than any other aerial, and, therefore, has less tendency to leak to the ground. This advantage comes especially into play when this type antenna is used for C-W work in transmission.

* * *

When high-frequency currents flow in a circuit, they travel on the surface of the conductor and are known as "skin effect." For this reason Litz wire and stranded wire are generally used in radio work where high-frequency currents are to be carried.

Cost of Installing a Set

A SIMPLE receiving-set which will copy commercial stations from a distance of 500 miles or more, is quite small. If all necessary instruments are purchased, the cost should be under \$50. When made by the experimenter himself, the cost of material is less. Experimenters who are really interested in "What it does and how it does it," find most satisfaction in mastering the details and operation of each instrument as they add to their stations. That is the way of the logical mind and, under cover of providing for real indoor sport, radio work offers to the younger minds valuable development in logical and analytical thinking—more effective than school-book methods since it is accomplished by real entertainment.

Radio-Wire Tables

By Frederick J. Rumford, E.E., R.E.

No. 3—Double Cotton-Covered Wire

Showing the Number of Feet in a Pound and Fractions of a Pound

APPENDED is the third of a series of five tables which the radio amateur will find useful for many purposes. The succeeding tables—"Single Silk-Covered Wire" and "Double Silk-Covered Wire"—will be published in early numbers of RADIO WORLD

Motor Car Receives Radio Messages

(C. Central News)

The above photograph shows a loop aerial erected on the roof of a motor-car. It was an important experiment conducted by the Marconi Wireless Telegraph Company of London. The set was installed in the center of the car in order that the lead-in wires from the loop might be brought to the set. Results were obtained thirty miles from a broadcasting station. Note this peculiar loop aerial. It can be rotated from the interior of the car, making it possible to manipulate the direction of the loop while receiving electromagnetic waves from a broadcasting station. Loop aeriels are being used by many radio amateurs. When the loop is employed, radio-frequency amplification or the well-known Armstrong superregenerative receiver must be used in order to get results. This loop has the distinction of eliminating interference, a marked advantage over the outside aerial.

Arlington to Be Government's Radio Broadcasting Center

WASHINGTON, D. C.—With 573 private broadcasting stations offering daily programs, the radio public is apt to lose sight of the fact that the United States is also broadcasting information on many subjects. Six departments are scheduled for daily or semi-weekly programs and forty-two Naval radio stations are carrying news of one sort or another.

Requests for permission to broadcast have become so numerous that the co-ordination of all government broadcasting has become necessary. A committee of twelve officials, representing as many branches of the government at Washington, is endeavoring to supervise matter submitted for public broadcasting over radiotelephone circuits furnished through the courtesy of the Navy Department. In order that the listeners-in may receive the maximum service with a minimum of interference and without duplication, this committee was appointed last spring at the suggestion of Herbert R. Hoover, Secretary of Commerce. It is known as the Interdepartmental Advisory Committee on Radio Broadcasting. Although the committee meets biweekly, its subcommittees are busy almost continually with this work.

Scope of Interdepartmental Work

Demands for broadcasting of telegraph matter, as well as telephone, are constantly increasing and the scope of the committee's work is gradually growing greater. Recently the question of broader activities and supervision has arisen, due to the frequent requests for investigation and advice on matters other than telephone broadcasting, originally the committee's sole function. Extension of activities is understood to have been generally approved by the different departments so as to cover the subject of radio communications, and the matter is now before the Secretary of Commerce for further action. It is quite probable that this committee will eventually become the statutory advisory committee provided for in the radio bills sponsored by Senator Kellogg and Congressman White.

Activities of the committee to date have made possible the broadcasting of several interesting programs from NOF, the Naval radio station at Anacostia, which is primarily the experimental radio station of the Navy's Bureau of En-

By Carl H. Butman

gineering. The Anacostia station, however, cannot carry the load and does not operate on Saturday afternoons, due to other official duties. As soon as arrangements are completed, all radiotelephone broadcasting for the government will be transferred to the big Arlington station.

Origin of Interdepartmental Committee

Last spring, when the popular demand for broadcasting reached its height, so many official and semi-official requests to use NOF were made of the Naval Communications Service that Secretary Denby could not grant them all; in fact, he finally ruled that only official messages could be transmitted. At one time, NOF was closed to all except the highest governmental officials. Suggestions that an interdepartmental committee be appointed to pass on broadcasting and supervise its operation, made by Secretary Hoover, therefore, were welcomed by the Navy Department. The committee began to function on June 1. Matter submitted for broadcasting is inspected and methods of operation arranged by subcommittees which attend to all details, determining the value and demand for particular broadcasts.

Applications for broadcasting by the Interior, Agriculture, Labor, Treasury, Commerce, and War Departments have been approved by the committee and fixed schedules, giving each applicant a maximum service of three fifteen-minute periods each week, have been put in operation. Many listeners-in throughout the country have undoubtedly heard the evening lectures and band music over the NOF phone on 412 meters.

The Government's Schedules

On Monday, Tuesday, and Thursday evenings, the Treasury Department broadcasts deal with the activities of the Public Health, Internal Revenue, and Savings Bureaus. The Commerce Department's schedule on Tuesday and Thursday evenings includes information on foreign and domestic markets, trade news, and fisheries. Talks on immigration, women's activities and child welfare are made on Monday, Tuesday, and Thursday evenings by officials of the Labor Department. The Interior

Department furnishes lectures on education and mining on Monday and Thursday evenings and Tuesday afternoons. Information pertaining to crops and weather is transmitted every Monday, Tuesday, and Thursday evening by the Department of Agriculture. Officers of the Department of War will shortly broadcast a series of talks on military activities and recruiting on Monday evenings. Sometimes special broadcasts are arranged for national associations, such, for example, as the series of speeches on Naval Activities by officers of the Navy, requested by the American Marine Association during its exposition in New York. The evening programs are so grouped as to make a compact schedule and not interfere with private broadcasting. Each week the programs will be announced by the Navy Department.

Arlington Chief Broadcasting Station on Two Waves

The opening of NAA, Arlington, as the official government broadcasting station, has been delayed due to difficulty experienced in operating on the lower governmental wave-band designated for telephone broadcasting. Very soon the Arlington station will open two telephone broadcasting circuits. It is a very busy station and it is necessary to operate several circuits simultaneously without interference. NAA's new broadcasting telephone set of 750 watts, recently installed, operates very successfully on the 2050-meter wave telephone circuit, using the main antenna, but does not give good results on the government's 490 wave due to reactions between other sets when in use. For this reason, the subcommittee on technical matters has been requested to consider the use of a wave length of 430 meters in this work. If it is approved, special permission will be requested of the Department of Commerce for its use, since it lies in the band assigned to private and toll broadcasting. The lower wavelength is believed necessary so that the service will be available to the people who do not own sets capable of picking up the long 2050-meter wave.

Code Broadcasting Extensive

Telephone broadcasting for the departments is not the only work handled by the Naval Radio stations; many messages are broadcast also in telegraph code. NAA car-

Transmitter That Slips Over the Head

By S. R. Winters

THE multitude of instruments in the cockpit of a modern airplane is graphically pictured in a recent diagram indicating that the pilot must manipulate or watch forty units of apparatus. The use of radiotelephony and radiotelegraphy in aerial navigation has enlarged the mass of instruments and controls, this communication service including a radiotelephone transmitter, radioreceiving tuner, wireless amplifying switch, radio-tuning condenser, wireless transmit-receive switch, radio-receiving helmet, telegraph key, and radio direction finder.

Obviously, then, the hands of the pilot are never off duty. Since the control levers for the actual manipulation of the air-going machine are likely to monopolize his hands, the use of the radiotelephone is possible while the pilot fingers with the throttle of the engine or other mass of instruments of the aircraft proper. Once the telephone receiver is placed directly over the ear canals, and the telephone transmitter is ad-

justed in front of the mouth, both the transmission and reception of communications may be negotiated while the thumbs and fingers are engaged in controlling the fortunes of the airplane. The accompanying photograph herewith shown illustrates a type of radiotelephone transmitter and receiver which snugly fits over the head of the pilot.

Contrary to the common system of transmitting wireless messages from ground stations, the hands are absolutely relieved from holding the telephone and they may be employed in making adjustments of the wireless apparatus proper or in manipulating the control levers of the flying machine. The helmet is made to

order; that is, each unit is designed for an individual wearer and the owner is cautioned not to loan it to others. The telephone receiver is adjusted directly over the ear canals and is fitted thereon snugly as a means of excluding vibrations of the airplane engine and other noises foreign to the incoming wireless signals.

The telephone transmitter is so adjusted in front of the mouth that the wearer can use it without causing him to bend his head. Close inspection of the photograph illustrating this type of telephone-transmitting device shows that it is not far removed from the lips of the operator. Voice tests have indicated that indistinct transmission of speech is produced when the pilot wears the transmitter too far from his lips.

This design of telephone transmitter may be conveniently employed for intercommunication between two airplanes, or a squadron of flying machines, or between aircraft and wireless stations on the ground. When used in connection with the transmitting circuit of SCR-68, a popular radiotelephone set of the Signal Corps of the United States Army, it operates thusly:

If no voice vibrations are impinged on this transmitter, the potential of the modulator tube grid remains constant. Consequently, there is no fluctuation in the electric currents of the plates of the two electron-tubes. However, when the pilot impresses his "gift of gab" on this telephone transmitter, a pulsating electric current is caused to flow in the primary circuit of the input transformer. This is the resultant action of the transmitter, which impinges on the grid of the modulator electron-tube an alternating or varying potential electric current following the modulation of the voice. Such variations cause corresponding changes in the electric current permitted to get into action in the plate circuit of the modulator electron-tube, and, therefore, in the plate current of the oscillator-audion bulb. Finally, these variations find their way into the amplitude of the oscillations in the circuit of the antenna. Consequently, the electro-magnetic waves radiated by this telephone-transmitting outfit, instead of being of constant amplitude, have an envelope reproducing the pulsations of electric current in the telephone-transmitter circuit. The electric waves are modulated to the speech.

The above photograph illustrates a type of radiotelephone head gear, consisting of a microphone and a set of ear pieces, which fit snugly over the head. This is a marked improvement in radio for operators who work aboard airplanes. It is possible for the operator to manipulate the controls, dials, direction finder, and key without holding a microphone, which had to be done prior to the use of this device. The microphone is so adjusted before the speaker's mouth that he can use it without bending his head. Close inspection shows that it is not far from the lips of the operator. Voice tests have indicated that indistinct transmission of speech is produced when the operator wears the transmitter too far from his lips.

(Continued from preceding page)
ries ten telegraph broadcasting schedules daily, totaling thirty hours each week and comprising, chiefly, quotations on foodstuffs for the Department of Agriculture approximating 35 per cent of its day's work. NAT, the Naval station at New Orleans, broadcasts two schedules a day, aggregating four hours a week; the Great Lakes station, NAJ, carries eighteen daily schedules, constituting thirty-six hours a week.

In addition to this matter, twelve Naval stations broadcast two time-signals daily; twenty carry hydrographic information; thirty-seven transmit weather forecasts; and six broadcast press matter. Sandwiched between these many schedules, the Navy carries on its own official communications, as well as many for the State Department, to ships and foreign stations, and is busy with experiments.

A glance at the operating schedule of any governmental radio station will explain why the government requires the service of the Interdepartmental Committee in an effort to simplify and standardize government broadcasting. Uncle Sam is not only generous with his information but he is also generous in his means for transmitting it to the country at large.

Broadcasting God's Word to Millions

By Peter Gray

IN the Beginning God," the first four words in The Holy Bible, was the text chosen by Reverend Ernest M. Stires, D.D., for twenty-one years rector of the Saint Thomas Episcopal Church, Fifth Avenue, New York, for his sermon, "The Inevitable Faith," which was the vital part of the first church service to be broadcast from a church edifice in Greater New York.

Dr. Stires became a radio enthusiast last winter after conducting a radio chapel service in WJZ's broadcasting studio in Newark. Various members of the Saint Thomas's parish who were out of town, as well as others, telegraphed, telephoned or wrote about the helpfulness of the service and the clear reception. The request was then made by the Westinghouse officials that they would like to broadcast services from the Saint Thomas Church. The suggestion was favorably received by Dr. Stires as he was overwhelmed by the immediate response of the invisible audience.

The Saint Thomas Church is con-

sidered by architects to be the finest example of Gothic architecture of very recent construction. The interior of the church with its wonderful pillars, beautiful pulpit, and exquisite altar and reredos is almost beyond description. A sound-proof brick ceiling makes the acoustics of the Saint Thomas Church almost perfect. The microphones are hidden so as not to detract from the church services. One is on the pulpit, near the Bible, for broadcasting the sermon, one at the lectern for the reading lesson, two on the chancel for prayers and solos, two at the altar for prayers, one on the balcony for the organ and choir, one in the hall for the processional and opening prayer and one for WJZ's announcer.

Dr. Stires in an introductory way in the second service to be broadcast said the Saint Thomas Church is much pleased and benefited by the instant expression of apprecia-

(C. Kadel & Herbert)

Dr. Ernest M. Stires in the pulpit of St. Thomas, New York, delivering a sermon by radio. Note the microphones on the lectern.

tion of the great world outside of the parish and that if any opposition had existed (there was none by the parish), it would have been dispelled by reading the letters piled upon his desk—some came from those who were ill for years and never expect to leave their homes, who said they were benefited and helped and were grateful; a group around a receiving set took up a collection and sent \$11.25 to help defray the church expenses.

A suburban resident, who used to attend church regularly, was working on his auto and, grease besmirched, listened in during the wonderful service, and did not feel free to break the silence of his home during the Communion any more than he would in church. Others stated that it was their habit to spend Sunday morning playing poker with friends. Now when 11 o'clock comes around, the cards are cast aside and the radio receiver set to work. And so with pipes alight they follow the service. Two instances of lazy ways to go to church but far better than not going at all.

It was not many months ago when there was a great diversity of opinion in religious circles about the propriety of broadcasting church services as it seemed almost sacrilege to broadcast prayers and hymns. That was before the first experiment was made, in the history of radiotelephony.

(C. Kadel & Herbert)

National Radio Week Is Gripping the Entire Country

WHAT it IS—NATIONAL RADIO WEEK is a movement to popularize radio, to double the number of broadcast listeners, to show the progress made thus far in broadcasting, to reveal new possibilities, to kindle the spirit of radio in as yet unresponsive breasts.

What it is NOT—It is NOT a movement by any one organization. It is NOT a manufacturers' drive. It is NOT intended to be anything but a thoroughly unselfish, co-operative effort, national in scope, exhaustive in material.

When it is to be held—December 23 to 30 (inclusive) this year.

The campaign is being directed by an executive committee, of which J. Andrew White, editor of "The Wireless Age," is chairman. Others on the committee are: H. Gernsback, editor "Radio News"; Arthur H. Halloran, editor "Radio"; Roland B. Hennessy, editor RADIO WORLD; Laurence Nixon, editor "The Radio Dealer"; and Arthur H. Lynch, treasurer, editor "Radio Broadcast."

Headquarters—NATIONAL RADIO WEEK headquarters are at 326 Broadway, New York City, N. Y.

What is to be accomplished—Every listener will endeavor to interest one person into a radio fan. This will double the number of broadcast listeners. Programs from every station in the country, specially prepared to fit the holiday season and the spirit of the week, will be sent out on the air. Sporting events, operas, jazz bands, speeches, and other particularly interesting programs will fill the air. Nation-wide broadcasts of a single event to be heard in every section of the country at once will be made.

Country-Wide Words of Praise

The following additional acceptances of places on the general committee, and expressions of approval for the campaign, have been received:

"Radio Journal," 113 Stimson Building, Los Angeles, says:

We are glad to put our shoulder behind National Radio Week. Our new editor, K. P. Frederick, is lining up local newspapers. Our general manager, Hugh Harlan, is getting support from local dealers. Mr. Frederick accepts the honor of being on your committee.

"Radio Topics," Oak Park, Illinois, says: We shall be glad to co-operate with you,

and in our December issue there appears a timely editorial. Our January issue, which will be out December 10, will also carry publicity of assistance to the movement. We should be very glad to have you include our name on the active press members.

"QST," Hartford, Connecticut, K. B. Warner, editor, says:

Our December magazine contains an editorial in which we have pointed out to our members the idea of doing what we can to boost radio during National Radio Week. I will accept a place on your general committee as the editor of QST.

Mr. H. Lewis, "Radio News," Toronto, Canada, says:

I will be only too pleased to co-operate with your committee in putting across a "Radio Christmas." I have been playing up this idea. I should be glad to accept a membership on your committee.

J. B. Taltavall, publisher of "Telegraph and Telephone Age," 253 Broadway, New York, says:

You are at liberty to add my name to your general committee.

Frederick A. Smith, editor, "Radio Age," Chicago, wires:

Pleased to accept membership on National Radio Week Committee. Will lend hearty co-operation through magazine. The idea is good.

Telegram from "Radio Digest," 123 West Madison Street, Chicago, Charles F. Smisor, editor:

Count me in!

S. Gernsback, editor of "Radio News," says in the December issue of his magazine:

December 23 to December 30, inclusive, is to be the first National Radio Week, suggested originally by Mr. Roland B. Hennessy of New York City. During that week every radio enthusiast should try to think, talk, dream and do it nothing else but Radio.

The object is to acquaint the public at large with Radio.

"Radio News" has prepared a beautiful colored post card which we shall be glad to send to every one who asks, in any reasonable quantities. This postal card, the picture of which will be published in the next issue of "Radio News," is to be sent to all your friends who are as yet

not interested in Radio, inviting them to come and see your station, or any first-class station of which you know.

This is a preliminary announcement, and we shall have more to say about National Radio Week in the January issue.

"The Evening Journal," New York, says:

The great part which radio communication has taken in the dissemination of education and entertainment and its service as a means of interchanging information is to be demonstrated by a co-ordinated program of the radio interests, in a country-wide undertaking to establish a National Radio Week as an annual event.

The effort to establish National Radio Week as an annual institution is backed by co-operative effort on the part of the newspapers, the radio press, manufacturers, dealers, amateurs and the great army of broadcast listeners.

The tentative program is arranged for the week December 23 to 30, inclusive. It is a most comprehensive plan to popularize radio with the public, and while only a general outline of the plan is so far available, it is known that it embraces programs of national, State and local character in which the 550 or more radiophone broadcasting stations of the country will take an active and important part.

Special programs to include the leaders among public officers, statesmen, educators and the musical and entertainment world in general are being arranged, all with the main idea of introducing radio to the uninitiated and firmly establishing it in its proper place as a recognized agency of bringing radio instruction and entertainment into the homes.

Under the heading "Hail National Radio Week and Help Put it Over Big," the "Radio Retailer and Jobber" says:

The idea was first announced at a luncheon of radio paper editors held at the Bankers Club, in the Equitable Building, 120 Broadway, New York City, early on a Tuesday afternoon in October last.

The innovation was seized upon with alacrity by all present and provision was made for a very formidable and well-balanced committee to sponsor the institution and make of it a crowning success.

The broadcasting stations were called upon to transmit the announcement that Radio Week was scheduled soon to come; thus saving a huge outlay in postage, though extensive circularizing has been provided for.

The broadcasting stations have also been urged to commemorate National Radio Week by particularly notable programs which would prompt listeners-in to look forward to Radio Week as an annual institution.

Every effort will be made to make Radio Week a national and not a localized innovation.

So one and all from coast to coast, and from the lakes to the gulf, with Canada thrown in, let us root for National Radio Week, and let us put it over with a great blare of trumpets, so that it may be a national institution, an annual visitor and a great stimulator of activity in the radio trade for many years.

Send in your Ideas for the
Success of
National Radio Week

Progress in Radio Devices

Approximately 3500 Patents Already Granted, 400 of Which Are Held by Fessenden, De Forest, and Stone

By *B. R. Cummings*

Radio Engineer, General Electric Company

THE fundamental phenomenon which is utilized in radiotelegraphy and radiotelephony was first demonstrated by Heinrich Hertz, the German electrician, in 1888, thirty-four years ago. Hertz, at that time, showed that it was possible to radiate energy through free space. He was not interested in accomplishing results over great distances, apparently not having conceived the idea that this phenomenon could be utilized as a method of communication, and his tests were carried on only over distances up to approximately 300 feet.

In fact, Hertz deliberately avoided using an earth connection in his apparatus, which would have immediately increased the distances over which he worked, believing that this would detract from his demonstration of the transfer of energy through space and that it would appear that the energy was being transferred by the conductivity of the earth. He was interested only in a pure demonstration in physics.

It is of interest to note, in comparing Hertz's equipment with modern radio apparatus, that his receiver consisted only of a single loop of wire which included a minute spark gap, and that his indication of the transfer of energy through space was the spark which jumped this gap when the so-called "Hertzian Oscillator" was in operation. His receiver, or "indicator," therefore, was extremely crude as compared with modern radio-receiving.

The Hertzian oscillator remained a laboratory instrument for a number of years, and was used only in connection with experiments in physics.

In 1894, Marconi, who was a wealthy young man with a scientific training, saw in the Hertzian oscillator a possibility of developing a new method of communication which would permit communication being carried on over areas previously considered impassable. Instead of avoiding the earth connection, as Hertz had done, he used it both as the transmitting and receiving stations and was immediately able to secure an indication of the transfer of energy over much greater distances than had been realized by Hertz.

The years immediately following 1894 were marked with intensive development on the part of Marconi, both of transmitting and receiving equipment, with gradually increasing ranges, until, on December 12, 1901, he succeeded in transmitting the letter S across the Atlantic from England to Newfoundland.

While Marconi, since that time, has contributed greatly to the advancement of the radio art, his greatest work may be said to have been completed at that time, for he had shown that the Hertzian oscillator, which had previously been considered only as an interesting laboratory experiment, could be used in establishing communication over great distances, and that the widespread use of this system depended only upon the further perfection of the apparatus utilized.

This accomplishment attracted the attention of scientists in all parts of the world toward "wireless," as it was then called. In the years immediately following, tremendous strides were made in improving the sensitivity of receiving equipments and in increasing the power radiated at the transmitting station.

The individual accomplishments in radio from this point on are somewhat hard to define, although several of the outstanding contributions to the art can be touched upon.

In 1884, Edison, and several years later, Fleming, discovered that it is possible to pass an electric current from a hot body to a cold body in a vacuum. This phenomenon was investigated by Fleming for a number of years. After he discovered that such a device would pass current in one direction only, and was, therefore, a rectifier, he secured a patent on it in 1905, the device being known as the "Fleming Valve." This valve was utilized in radio-receiving circuits as a detector and was a tremendous improvement over previous forms of detectors.

Shortly thereafter, Dr. Lee de Forest obtained a patent on a device which he called the "audion" and which was essentially the Fleming valve with a third electrode by means of which it was possible to control the current flowing in the tube.

Strangely enough, in spite of the

progress made in these devices, which are grouped under the heading of "vacuum tubes," comparatively little was known of exactly what takes place in them. A number of years elapsed before their functioning had been analyzed.

In 1915, Armstrong made known what has since come to be called the "feed-back" circuit, by means of which the detection and amplification of received signals, by a single tube, was made possible, and also by means of which the three-element vacuum tube could be made to function as a generator of alternating current, making possible the modern vacuum-tube transmitter.

Although radio broadcasting is a recent development, radiotelephony was first accomplished as far back as 1905, and the broadcasting of music was successfully carried on by de Forest as early as 1914. Practically no interest was shown by the general public in broadcasting at that time, and his concerts were discontinued. Broadcasting has also been carried on, although in the Continental code, by the Navy Department station at Arlington, Virginia, which, since 1915, has been transmitting time signals, weather forecasts and news events each night after 10 o'clock. It has been from Arlington's transmission that ships at sea have been able to print daily newspapers.

To indicate the great number of devices and circuits which have been developed for radio communication, approximately 3500 radio patents have been granted up to the present time. Naturally, some means have been much more prolific in this respect than others; and three men, who were most active in the early days of radio, Fessenden, de Forest, and Stone, hold among them a total of nearly 400 patents.

And yet, the tremendous amount of research and development work which has been done in advancing the radio art has only served to indicate fields and applications for this method of communication which have as yet been unexplored. It seems assured that radio will eventually find its place as a public utility and be utilized to an extent far surpassing any of the other existing methods of communication.

The Radio Primer

*For Thousands of Beginners Who
Are Coming into Radio Circles*

Weekly A B C of Radio Facts and Principles Fully and Tersely Explained

By Lynn Brooks

I*S all electricity made up of electrons?*

All electricity is made up of electrons. You will get a correct idea of electricity if you try to visualize it as being made up of electrons. Everything contains electricity; in other words, everything contains electrons.

* * *

What are electrons?

An electron is a minute negative charge—it is but the smallest fraction of an atom. A negatively charged body has more than its usual number of electrons. A positively charged body has less than the usual number of electrons.

* * *

How do these electrons flow?

Electrons flow along a conductor when that conductor connects objects, or points, which do not have the same share of electricity, not the same amount of electricity. One body may have a greater amount of electricity than another and yet have the same share in the same way as if a grown man and a two-year-old child were sharing food. The man would have a greater amount of food than the child, and yet he would have shared it with the child. In electricity the size, shape, and other elements of a body determine what the share should be.

* * *

How many ways are there in which an object may have a different share of electricity?

There are five ways in which an object may have a different share of electricity. One object may have more than its usual number of electrons and another object less than the usual number. Electrons will travel until both have the same share. Still there are four more ways in which an object may have a different share of electricity. Years ago, before much was known about electricity, it was understood that something "flowed" along a wire. The men studying electricity then agreed to say that it "flowed." They had an even chance of being right, but they made the wrong guess. The word has not been changed. To do so now would only create confusion. In a similar sense, we state that the sun rises. It is a stationary body. The earth moves. However, electricity "flows" along a wire from one end to another. The force of this is called "voltage."

What is voltage?

Voltage between two points measures the effort which the electrons make to move from one point to another. The effort which electrons make to move from one point to another depends on the difference in the proper share of electrons in excess of the other. The greater the difference in the share of electrons, the greater the voltage. However, we do not measure voltage by saying that one point has a certain number of electrons in excess of the other. It is measured in volts. This is somewhat

Schematic diagram of a conductor across a plus, or positive line, and the minus, or negative, side. Its duty in radio is to carry the electrons from pole to pole. In radio work this is termed a short circuit. Drawn by Lynn Brooks.

similar to the fact that we do not buy beans by ordering a certain number—we buy them by the quart. When you speak of voltage you must have two points in mind. Voltage is an expression of the effort made by electricity to get from one point to the other. It is measured in volts.

* * *

How do the electrons travel?

Electrons travel, or try to travel, from the point which has the greater share of electrons to the other point. As the point which has the greater share of electrons is negative (—) and the other point usually positive (+), the electrons travel, or try to travel, from negative to positive. The current is said to flow in the opposite direction—that is, from positive (+) to negative (—).

* * *

What is necessary to produce an electric current?

If we can keep a point so that it will always have more than its usual number of electrons (—), and another point that will always have less than its usual number of electrons (+); and if we connect both points by a conductor, we will have the condition necessary to produce an electric current.

How to Determine a Detector Vacuum Tube

TO determine a detector tube from an amplifier can be accomplished only by experiment. Place the detector tube in the amplifying socket and use from 45 to 60 volts of plate potential. Turn on the filament current and pay close attention to the results. If the tube should happen to turn blue, turn off the current at once. This test will show that this tube is a soft tube and should be used as a detector and for detecting purposes only. In case the blue glow is not present, it is a sure sign that this tube is an amplifier of the hard-tube class.

What Is Meant by Coupling

THE object of loose coupling is to eliminate the effect of interference by loosening the coupling between the two coils, the primary and secondary. It has been found in practice that when the primary and secondary circuits are in resonance with each other, the primary and secondary coils may be separated quite a distance and signals still be recorded in the telephone receivers; whereas signals that are not in resonance with the circuits will be eliminated by widening the coupling between the primary and secondary.

The Tickler Coil's Use

THE tickler coil is a coil of wire placed in inductive relation to the primary and secondary circuits of a receiving set. The tickler itself is in the plate circuit of the vacuum tube and affords a feed-back system that produces regeneration. The function of the tickler is best explained by describing what happens if you take the telephone receiver from the hook when the bell is ringing and then place the receiver to the transmitter. The result will be a continued "howling." This is regeneration. In a radio circuit, the tickler coil produces regeneration.

The Radio Primer has been published regularly in RADIO WORLD since issue No. 1, and will be a regular department in order to instruct and aid the many thousands of amateurs who are joining the ranks of radio enthusiasts every week.

Radiograms

Latest Important News of Radio Garnered from the World Over, and Reduced to Short Wave-Lengths for the Busy Reader.

MAJOR GENERAL JAMES G. HARBORD, deputy chief of staff of the United States Army, on his retirement will become president of the Radio Corporation of America. General Harbord was elected head of the Radio Corporation at a recent meeting in New York. His retirement from the Army will be effective December 29, Secretary Weeks announces, and he will assume his new duties on January 1, 1923. Edward J. Nally, president of the Radio Corporation, it is announced, has been elected to a new office—that of managing director of International Relations, with headquarters in Paris.

* * *

The Mexican Government is about to receive four powerful radiotelegraph sets, which are to be presented to the republics of Guatemala, Honduras, Costa Rica, and Nicaragua in accordance with the decision of the president of the Republic.

* * *

The London Free Press of London, Canada, recently opened its broadcasting station. Its call letters are CJGC and its wave is 430 meters. At present its power is derived from two 50-watt oscillators.

* * *

Probably no other broadcasting station in the country can claim the distinction recently achieved by station KSD, San Francisco. A concert was sent out from this station, which was heard in every State in the Union.

* * *

A radio message, picked up at the Santiago Station of the Naval Wireless System and relayed from San Francisco, purporting to come from Hilo, Territory of Hawaii, told of an earthquake and tidal wave there. Efforts to communicate with the Hilo Radio Station, operated by a private concern, later were unsuccessful, but radio men declared it was not usual for that station to communicate direct with mainland stations.

* * *

The completion of the new radio station at La Prairie, Canada, will connect Sydney, Australia, and London.

* * *

The United Fruit Company has announced the inauguration of a free medical radio service from its hospitals in the various countries of Central America and from its passenger steamships to all ships at sea. This service is to be available without charge to ships of all nationalities through the following radio stations operated by the United Fruit Company and the Tropical Radio Telegraph Company: New Orleans, WNU; Burwood, Louisiana, WBW; Fort Morgan, Alabama, WIO; Swan Island, US; Tela, Honduras, UC; Puerto Castilla, Honduras, UA; Tegucigalpa, UG; Port Limon, Costa Rica, UX; Almirante, UB, and Santa Marta, Colombia, UJ.

* * *

To London and back, by radio, in 45 seconds! To Berlin and back, by radio, in 2 minutes and 40 seconds! These were the records made at the Engineering Societies Building, 26 West 39th Street, New York City, on Wednesday evening, November 22, during a discussion on radio by David Saranoff, vice-president of the Radio Corporation of America. "How's the weather?" was the query flashed across the Atlantic. Within three minutes the members of the society heard the dot and dash replies hurled back through the night from three countries of Europe. Within forty-five seconds London's answer came

in: "Raining, mild." Ten seconds later came the reply from Norway: "Overcast, mild." France was third with: "Lovely weather," and Germany came last, two minutes and forty seconds after the question. She answered, "Gloomy, cold," and then added, "Greetings." A new development in radio, which Mr. Saranoff predicted would come soon, he described as the "wrist-watch wireless set or radiolet." "Such a set could be carried easily on the person," said Mr. Saranoff, "and signals could be received from stations twelve or fifteen miles distant, thus a man could receive in his vest pocket market reports, weather reports and details of championship games."

* * *

Amateur long-distance radio records were shattered at the radio station of Hiram P. Maxim, president of the American Radio Relay League, when a radiogram was sent to Clifford Dow, Waikiki, Hawaiian Islands, and the answer was received in 4 minutes and 18 seconds. The radiogram was relayed at Sleepy Eye, Minnesota, by Lloyd V. Berkmer. The distance from Hartford to Sleepy Eye by air line is about 1,200 miles, and thence to Wailuku 4,000 miles.

* * *

Cavalry Church, Pittsburgh is using radio-receiving sets as an extension work.—"Our parish is now doing organized work by wireless," said Dr. E. J. Van Etten, the rector. "We now have receiving sets. On certain nights, the Church Home is hearing our service through one of them. Two invalids are hearing these services through smaller sets in the hands of the new Calvary Radio Club. We send greetings of others who every Sunday night hear these sermons."

* * *

For the first time symphony music by a large orchestra has been broadcast by radio direct from the theatre.—That distinction falls to the Capitol Grand Orchestra, New York, whose performance of Richard Strauss's symphonic poem "Fun Heldenleben" was broadcast recently. The American Telephone and Telegraph Company, which perfected the sending, pronounced the achievement successful in every respect. The music was heard over a radius of 1,000 miles and over 600,000 radio sets caught the concert. The feat was accomplished by a highly sensitized microphone suspended from the roof, by which the sounds of the music were amplified and carried over equalized telephone wires to station WEAJ and then sent.

* * *

Radio communication is successfully used on airplanes to communicate to military bases from the air or enemy territory. The apparatus comprises a small sending and receiving station of light weight. Remarkable success has been attained over long ranges with radiotelephone, radiotelegraph, and direction-finding equipment. The receivers are provided with sound protectors, but receiving is less successful than sending because of the propeller noise. This defect has been overcome to some extent by using sound insulated telephone-headpieces. The aerial is generally, mounted on the planes and a counterpoise or additional aerial is used instead of a ground.

* * *

The first dress rehearsal of a theatrical performance to be broadcast by radio is also reported.—"This Little Kangaroo," the new musical comedy with James T. Powers, has been arranged was sent out by WJZ from the Morosco Theatre, New York. This important radio event took place at 5:30 p. m., November 22.

Getting Ready for the Big Show

S. H. FAIRBANKS, who managed the recent successful Radio Show in Boston, has been retained as advisory director by the management of the American Radio Exposition. This apportionment will be held in Grand Central Palace, New York, December 21 to 30, inclusive, and from present indications will far surpass any radio display of the past. Mr. Fairbanks will take charge of exhibits, the appointment of space, and other details of staging the show. L. S. Byers, executive secretary of the committee in charge of the show, will continue with the program of organization. A series of novel and sensational features are be-

ing worked out at present to make the exposition unusually interesting to the general public, as well as the fans and those unfamiliar with radio.

A number of new exhibitors contracted for space during the past few days. These include the Electric Storage Battery Co., A. H. Grebe & Co., Jewett Manufacturing Co., Newark, N. J., and the Burgess Battery Co. Exhibits are promised by the Western Electric Co., Inc., The Radio Corporation of America, and the National Carbon Co.

For economical reasons, practically all industries holding yearly expositions have learned that the East will support only one exposition a season, with perhaps one in the Middle West and one in New England. In view of the importance

of the metropolis as an industrial and export center, the numerous manufacturers exhibiting are talking co-operation in one big annual New York event, staged in a manner that will mean profit to manufacturers and dealers alike, and attractive to the public.

Held in 'Radio Stock Deal

MRS. MYRON CLEVELAND HARRIET SIMS, a stock broker, alleged to have sold stock in a radio company under misrepresentations to women investors, was held in \$7,500 bail for the Grand Jury when arraigned before Magistrate Joseph E. Corrigan in West Side Court, New York. Mrs. Sims denied the charges.

Radio and the Woman

By
Crystal D. Tector

ONE of the leading doctors of New York City took me through his hospital for children the other day. He is the head physician and guiding spirit of this institution; and he has decided to put a radio set in every room—not one set in the building, but, actually a set in every room! He said that he had read so much about radio being such a wonderful source of entertainment that he decided to see if the reports were true. He visited several institutions where radio is used as a means of entertaining the inmates, and came to the conclusion that the reports were in no wise exaggerated.

* * *

I was called in because he really knew no one else who might give him some advice. Immediately he decided that radio was a necessary element of his institution. He rushed to a newsstand, he says, and purchased a copy of RADIO WORLD. He opened the paper to my page, and, he continued, "as a matter of luck, I sent for you."

* * *

I gave him the names and addresses of several experts who will fit him out—who will install in each of the sixty rooms of his hospital just what he needs in the way of radio reception. But this fact is neither here nor there. It is a purely commercial matter in which I am not interested. I am only thinking of the big, human, charitable idea back of it all. I am extolling this man for thinking of someone else—of his willingness to go to any expense, as he told me, that the little sufferers in his care might have some entertainment to relieve their hours of convalescence.

* * *

Children—and grown-ups, too,—have suffered from the beginning of time; and as the world has progressed, and, little by little, efforts have been made to relieve their suffering. Here, in the midst of the first lustrum of this benighted century, comes the happiest method of all—the bringing to little bedsides where patient sufferers lie, the wonderful and fascinating things that come over the ether. I think that the success of this doctor's experiment will urge other institutions to follow suit. I make the prediction that it won't be long before every hospital in this country is installed with radio—and that radio will be as necessary to it as the doctors themselves.

* * *

And as the gladsome time of the year approaches, what can be of greater satisfaction to this man of medicine, this eminent diagnostician, than the fact that he is not purchasing a few trinkets and toys that will be cast aside as soon as they are broken—that he is not doing something that will please only his little patients of today, but that he is building, for all time, for the unfortunate children of the future who will come into his care. And as radio is improved and its scope becomes wider, there will be special broadcasts for hospitals—stories, and songs, and messages of cheer, and church services for all—young and old—who are temporarily incapacitated.

* * *

More power to this good doctor.

* * *

In reply to several correspondents: It is not difficult—or, it should not be difficult—to start the nominating for the offices of a National Radio Week committee. You say that when it comes to nominating a chairman, no one seems inclined to start the ball rolling. Why not all speak at once? Now, I don't mean to be funny; I am just trying to be practical. Out of this method, some one is bound to be heard and the temporary chairman, if she has any pep, is bound to recognize one of the speakers.

* * *

Mrs. A. H. L., Walla Walla, Washington—By all means give your husband a radio set for his Christmas. I assure you that radio is not "wholly a man's field," as you write. I cannot praise it enough as a source of entertainment for women as well. And as for the children—well, if your boy "has not taken to it as yet, and seems wholly uninterested," all I can say is that something is wrong somewhere. You get the set and, about a month later, write me what effect it has had on the family.

* * *

Miss Hattie Kane, Harrisburg, Pennsylvania—Your idea of a red-white-and-blue ribbon with the letters N. R. W. thereon, to be worn during the big week is splendid. But why not the word

Woman Electrical Engineer Constructs Own Radio Sets

(C. Kadel & Herbert)

Miss Elizabeth Martrodge, of Exeter, England, is one of the few women electrical engineers in the world. Aside from this distinction, she is the inventor of a number of electrical appliances, and, to-day, is undertaking the installing of electrical lighting sets in country houses. However, since radio came into prominence in her country, she has "fitted up," as they term it on the other side of the Atlantic, a number of radio sets for "listeners in." Miss Martrodge is, perhaps, the pioneer woman radioist of Great Britain. She believes in it heartily and has done much to promote interest in the new science and to give valuable advice in order to help the British Government in its broadcasting problems. Miss Martrodge is shown in the photograph with her petrol-lighting set—petrol, or gasoline, being used there for heating country houses.

"RADIO"? You say that the ribbons are to be worn by women. Now, we want radio week to be the means of bringing thousands of fans into the fold and there are many so totally uninitiated that they might think N. R. W. stood for New Republic of Women, or something like that. With but the one word—"RADIO"—pinned jauntily to each feminine breast, the big idea is at once indelibly stamped and no time is wasted making explanations.

* * *

Vast possibilities of radio broadcasting are demonstrating themselves every day. In fact, every hour brings forth some new achievement for the great invention. For instance the postman delivered, several days ago, the following letter, which was addressed to the studio manager of WLW, the broadcasting station being operated by the Crosley Manufacturing Company:

Studio Manager, WLW

Dear Sir:

I am sick in bed, and my mother has moved my radio set into my bedroom so I can listen in. I enjoy this very much and sure get WLW very loud and clear. My collie dog likes to listen in, too.

Yours sincerely,

J. CLYDE FOX.

2640 West Sixth Street, Cincinnati, Ohio.

You who are in good health and enjoy listening to concerts, close your eyes a moment and picture this boy who, we have learned, is but 14 years old, lying in bed fighting off an attack of diphtheria and still reaping the harvests of pleasure that WLW is sowing. Also picture this boy's dog beside him, with head phones at his ears, and sharing the enjoyment of his little master.

What is believed to be the first municipal station on the roof of the Chicago City Hall as station, with the call letters 9 XAM. For messages, but in March, 1922, it was entered

(C. Underwood & Underwood)

(Left) Newspaper men reporting the Dartmouth-Cornell football game by radio. How times have changed! Up to a year ago, we had to wait until the papers came out next day before we could tell about the plays of each big game.

(Right) Professor John Hassett Vegessy, of Fordham University, at the receiving set of that institution. The radio students at Fordham are fortunate in having some very fine radio equipment. This photograph shows their receiving station. On the left is a very interesting regenerative set of the "composite" type that covers a wave-length range from 150 to 16,000 meters. There are three distinct sets in this cabinet, the first being used for 150 to 550 meters, the second for 550 to 5,000 meters, and the third (using honeycomb coils) for 5,000 to 16,000 meters. Most of the large foreign stations, including Poz, Germany, have been picked up by this set.

(C. Kadel & Herbert)

Important Part in the Service of the World

miniature vacuum-tube shown in this photograph, it is the smallest ever made. It is less than half the size of the "audion tube," invented by Dr. Irving Langmuir. It has a plate, grid, and filament. It operates on a small dry-cell battery. It is claimed that it will bring in signals loud and clear. It was used by a New York radio amateur solely for experimental purposes in a miniature pocket vacuum-receiver which he is entering in a contest. An idea of its small size may be gained by comparing it with a regular radiotron tube shown in the same photograph.

Another wonderful miniature radio set—one that may be carried in a camera case. It will fit into a small kodak case and may be carried by the owner on his travels. It has a transmitting range of about three-fourths of a mile and a receiving range of about a mile. Note particularly the miniature tube and the microphone. The dry batteries may be carried in the camera case. Mr. Sterling G. Sears, who built the set, is shown in this photograph. He is talking into the small microphone that is attached to the set. This is another view of the receiving set shown on our front cover.

(C. Kadel & Herbert)

(C. Keystone View Co.)

(Right) The Prince of Wales, now an ardent radio fan, is broadcasting a message to 60,000 boy scouts in his country. He is photographed speaking into a field telephone, his words being carried by wire to Marconi, London, and from there broadcast over Great Britain.

station in the United States, was established in June, 1921, and operated as an experimental station. At that time the station was used merely for local broadcasts. Its call is WBV.

(C. International News Reel)

(Above) The transmitting room of station WWZ, Wanamaker's, New York City. This station which works on a 300 meter wave-length is equipped with a vacuum-tube transmitter of the Western Electric type. The operator is shown here adjusting the transmitter to maximum signal strength. On the table is the power amplifier and loud speaker. This station also uses a power voice-amplifier. Without this device success in broadcasting would be questionable; but this new device is able to convey, without losing even the fraction of a sound, music and the human voice—from any place where they may be produced—to the broadcasting apparatus, where it is generated into radio high-frequency currents and sent broadcast.

(Continued from preceding page)

also 90 turns wound on the same tube at 1 and taped every 15th turn for tickler inductance, a 4 $\frac{7}{8}$ -inch rotor, wound with 90 turns of No. 24 on the same end, and in plate circuit on other end of the coil. I have a sliding secondary 4 $\frac{7}{8}$ inches in diameter wound with 320 turns of No. 24 enameled wire. The switches are provided to use either loose coupler, vario-coupler, or both. I have a 23-plate condenser in aerial circuit, and a small fixed condenser across phones. My aerial is a 3-wire, 86 feet long and 38 feet high. I have heard KSC, San Jose, California; KQA, Denver; the Fort Worth, Texas, "Journal"; WHB, Kansas City, Missouri; CJCE, Vancouver, B. C., and WGY, KDKA, WSB, WOC, and KSD regularly. Some say that my set is a freak; but it delivers the goods and is always under control.—J. T. Cavanaugh, 1024 Leahy Street, Muskegon Heights, Mich.

83 Stations, His Record

EDITOR, RADIO WORLD:—From 5 o'clock until 11 o'clock p. m., I average from 15 to 18 stations. Last election night, from 5 p. m. to 3 a. m., I caught 30 stations giving election returns. I keep a map and log. My record to date is 83 stations outside of the State of Georgia, including Canada and Cuba. The words and music come in clearly. I operate a one-tube home-made short-wave regenerative set with vario-coupler and two variometers, mounted on back of panel, and a variable condenser. I also use a 6-wire cage-aerial, 80 feet long, 50 feet high, north and south direction. The diameter of the cage is 12 feet. My lead-in, which is a 6-wire cage, is 50 feet. My counterpoise is a 3-wire, 80-foot, mounted 8 feet from the ground. I invite anyone to write me about my hook-up.—James L. Fischer, 72 Spring Street, Newman, Georgia.

Claims the Record

EDITOR, RADIO WORLD:—I have read with interest the letters from Mr. Merklein, Mr. McKinley and Mr. Miller, each giving their receiving records on one tube. I think I can beat their records. Using a two-variometer type set, one detector tube and 48 volts, I receive the following loud and very clear: WGY, Schenectady, New York; WDAP, WJAZ, and KYW, Chicago; WOC, Davenport, Iowa; WNB, Kansas City, Missouri; WGM and WSB, Atlanta, Georgia; NOF, Anacostia, D. C.; WJZ, KDKA, WBZ, WOR, WIP, WEA, WBAY, WHAZ, WWJ, WNAC, WQAA and others in New York State and other States. These are all heard on a 4-wire inverted-L aerial 40 feet long and 35 feet high, 15 feet above a tin roof.

With the same set and tube not lit to extreme brilliancy, with no aerial connection, only ground connection, I have heard WGM, WSB, WOE, KYW, WDAP, WGY, WJZ, WBAY, EEF, KFAF and 2X1 very plainly. I think this record can surpass any of those RADIO WORLD has published.—E. Sherow, Box 365, Millbrook, New York.

Takes His Set with Him

EDITOR, RADIO WORLD:—I have been reading in RADIO WORLD of the excellent results accomplished by other "radio-phans." Messrs. Merklein, Brooklyn, New York; W. G. McKinley, Bayonne, New Jersey, and E. L. Miller, Chappaqua, New York, seem to be doing very well, indeed.

I am a resident of Brooklyn, down here on business, and have my set with me.

It consists of the conventional vario-coupler, variable condenser, variometer, detector and one stage of a. f. I only use 22 $\frac{1}{2}$ volts for the detector and 45 on the amplifier. Why waste the power?

I am surrounded by high hills. My aerial is a single wire, 115 feet long and only 14 feet above ground. A 440-volt lighting line passes 5 feet above it, and a 5500-volt power line is less than 50 feet away. The aerial also passes close to the roof of an electrically operated printing plant, and is parallel to a 220-volt light line and a couple of telephone lines. In spite of these handicaps, my set "does its stuff right niftik" every day and night.

I have received concerts from more than 45 stations in 17 different States and Canada. These stations are from 59 to 1169 miles distant (accurately measured air-line). My best reception is from stations upwards of 560 miles. On the night of November 9, I received music from 18 stations in 13 States from Massachusetts to Minnesota, and from the Mississippi Valley to Texas.

Here are some of the fellows I hear every time we are on the air together:

KDKA, Pittsburgh; WOO and WIP, Philadelphia; KSD, St. Louis; WOS, Jefferson City, Missouri; WDAF and WHB, Kansas City, Missouri; WWJ, Detroit; KYW, WDAP, and WMAQ, Chicago; WBAP, Fort Worth, Texas; WLAG, Minneapolis; WFAC, Superior, Wisconsin; WKN, Memphis, Tennessee; WSB, WGM and WDAJ, Atlanta, Georgia; WOC, Davenport, Iowa; WGY, Schenectady, New York; WGI, Medford Hillside, Massachusetts; WBZ, Springfield, Massachusetts; WNAC, Boston; also WJZ, WEA and WOR, the ones I hear most while at home in Brooklyn.

I can easily tune out KDKA which is only about 59 miles away and very powerful.

Frequently I use a small funnel for a megaphone loud-speaker while receiving WWJ, and WHB.

My set is home made (by myself) and I have not yet soldered the connections. Some nice cold evening I hope to hear something from the Pacific Coast! Until then.—John S. Frampton, Spangler, Pennsylvania.

Good Detector-Tube Reception

EDITOR, RADIO WORLD:—I get KHJ (Los Angeles, Cal.) regularly, having had them five evenings this week: DNA of Denver, also Winnipeg, Canada, and Havana, Cuba. I receive many other stations at 1,000 miles and over. All this is being accomplished while experimenting on a detector tube without amplification. I don't just get them and hear the call, but I get as much of the broadcasting as I care to hear. Without amplification, I think this record is pretty good for detector-tube reception.—H. S. Rahiser, Box 43, Crafton Station, Pittsburgh, Pa.

Harlem Club Wants Members

THE Radio Club of East Harlem was organized September 20, 1924, the following officers being elected: Harold Itzel, president; John N. Itzel, secretary; John D. McEvily, treasurer; William Bogdel, instructor. The main object of the club is to bring together radio amateurs living in the district from 125th Street to 166th Street, east of Fifth Avenue.

The present total membership of the club is fifteen, and as the membership is limited to thirty-five, there is room for twenty more members. Write the secretary, John N. Itzel, 175 East 111th Street, New York City.

No Wireless Receiving set complete without it

Make it the **GREATER Radio Christmas**

This year the message of Christmas will flash one inspiration over all lands and to all peoples — no frontier can turn back the swift messenger, Radio, whose steed keeps pace with light.

The gift of all gifts is Magnavox Radio, the Reproducer Supreme: the gift that will mean most to every member of the family, old and young.

Let Magnavox bring you daily the world's news and entertainment — the greatest victory of science, the greatest opportunity of art!

R-2 Magnavox Radio with 18-inch horn: this instrument is intended for those who wish the utmost in amplifying power; for large audiences, dance halls, etc. . . . \$85.00

R-3 Magnavox Radio with 14-inch horn: the ideal instrument for use in homes, offices, amateur stations, etc. . . . \$45.00

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Radio.

2 Stage AC-2-C . \$80.00
3 Stage AC-3-C . 110.00

When you purchase a Magnavox product you possess an instrument of the highest quality and service.

Magnavox products can be had of good dealers everywhere. Write us for copy of new illustrated booklet.

Answers to Readers

PUBLISH a hook-up for a short-wave regenerative receiver consisting of a vario-coupler and two variometers to a one-step of radio-frequency amplification; also a detector and two-stage amplifier of the audio type. I intend to use filament-control jacks. I would like to use this set for long distance. I have a V-T 1 and 3 V-T 2 vacuum tubes.—George Buser, Springfield, Mass.

Radio-frequency cannot be employed with the variometer type of receiver. Radio-frequency is a different hook-up entirely and is of a different principle. In RADIO WORLD, No. 19, dated August 5, also in No. 24, dated September 9, are some very interesting diagrams of radio-frequency amplifiers. These hook-ups for one tube, two tube, and three-tube radio-frequency amplification.

Give me a hook-up for a receiving set using Myers tubes and vario-coupler, grid variometer, plate variometer, and detector.—W. A. Lewis, Ashtabula, Ohio.

See above reply to Mr. George Buser.

I have just bought a crystal receiver. I would like to know if there is any chance of increasing the mileage of this set so I can

hear stations of greater distance?—Carl Righter, Jr., Davenport, Iowa.

You may increase the range by adding a two-stage amplifier to your crystal set. Get a vacuum-tube detector and make your set regenerative.

Can a tickler coil be used with a crystal set? How many plate-variable condensers should be used with a double-slide tuner set? With a loose coupler?—Paul Moller, Schenectady, N. Y.

A tickler coil cannot be used with a crystal set. The number of plates that the variable condenser should have depends on how you intend it for. A condenser having 43 plates, or one rated as having a capacity of .001 microfarads, will give quite a range of wave lengths. It is best not to use a condenser of very large capacity across the secondary of a loose-coupler when a crystal detector is used. More than .0005 mfd., is not advisable for this purpose.

I have a set consisting of loose-coupler and a crystal detector with variable and fixed condensers which I intend changing into a vacuum-tube receiver. Is it better to discon-

nect the loose coupler entirely and construct the set with a tickler coil; or would you advise adding a variometer and variable condenser to the loose coupler?—Harold Johnson, Milwaukee, Wis.

This depends entirely on the range of wave-lengths on which you desire to work. If you want a set covering all wave lengths, the honeycomb coils or spider webs will be best. But if you want a set solely for short waves, the loose-coupler set might be better.

I am using a two-stage hook-up. I would like to substitute a 1½-volt detector tube for a U-V 200 and still use the U-V 201 as amplifiers, also to add variometers to grid and plate circuits.—Michael Baschia, Coney Island, N. Y.

It will be all right for you to use the 1½-volt tubes in your set provided you use separate battery circuits entirely for the detector and amplifying sections. Use the dry battery to light the tube of the detector and a separate B battery. The input to this section can be led from the place where the telephones are in the detector-circuit unit. You can add the variometers in the usual manner.

The radio set I purchased last month was going along all right until something happened and I didn't get a peep out of it. Looked it over—but cannot find any loose connections. The batteries are still new. I have some German condensers with a 2,000-adjustable clearance space between plates.—Maurice Kaplan, N. Y.

It may be possible that your condensers are short circuited at certain points, due to metallic dust between the plates. This sometimes happens, especially in condensers where the clearance is so small. Test them by joining them in series with the wire connected to the buzzer, then varying the condenser. Should the buzzer work, it will indicate that the condensers are short circuited. Clean the plates carefully or ascertain just where the shorting takes place. Your connections are all right.

With my home-made detector, I hear most of the local stations. Sometimes I hear WGY faintly. Enclosed find my diagram and aerial. Is there anything I can add to increase the range of my set? Possibly I may add something that will help me to tune better.—Alvin Jones, Syracuse, N. Y.

Your results are very good for a 4-wire aerial, 50 feet long. Your location must be high and unobstructed. You might try the .001 mfd., variable condenser in series with the tuning coil and then use more inductance to get the same wave length.

Is it possible to hookup regenerative circuit with honeycomb coils or D-L coils instead of variometers or vario-couplers? Can I use two WD-11 tubes in the above circuit and hook it up as one step of radio-frequency and one stage of audio-frequency?—L. C. Edgar, Detroit, Mich.

It is possible to hoop up a regenerative circuit with either of the honeycomb coils or the duo-lateral coils. Using the W D-11 tubes as radio-frequency amplifiers is impossible. They will not stand up for radio-frequency amplification.

Please publish a schematic diagram for a two-step audio-frequency amplifier using spider webs—primary, secondary, and tickler—one 43-plate condenser and one 23-plate condenser.—Wendell Weiss, Cranford, N. J.

This circuit was published in RADIO WORLD, No. 24, dated September 9.

One circuit I never found in any radio magazine is the superheterodyne. I would appreciate an article and hook-up of this set.—J. F. Swan, Seneca Falls, N. Y.

An illustrated article showing the panel, front, and back view of this set with a complete hookup was published in RADIO WORLD, No. 28, dated October 7.

In the Good Old Winter Time

(Cartoon by Harry J. Stillman)

Too Late!

From "The Chronicle," San Francisco, Cal.

What Radio Now Offers

SIX months ago any discussion of broadcasting brought up the subject of the quality of the programs which to some seemed below the average. Today the same general subject is widely discussed, but the particular phase on which emphasis is placed is the interference between good programs. Without a doubt the broadcasting stations are putting on features without a parallel in the worlds of art, literature, and sport, says "The Globe," New York.

With the broadcasting of the Chicago opera season called a great success both by listeners-in and the management of the opera, and with the recent broadcasting of the New York Metropolitan stars in the opera "Aida," the American stay-at-home public is being supplied with the finest operatic art in this country, and, perhaps the world. Between the areas covered by the two stations through which the Chicago and New York operas were broadcasted the most famous operas have been made available to two-thirds of the people of the United States and Canada.

From operas to sporting events is a long jump but no feature of broadcasting has been followed by so many fans as the successful broadcasting of the world's series baseball games and the football contests between the big colleges. When a big corporation decides it worth while to tie up two 900-mile long distance telephone lines for three hours while play by play reports of a football game are sent over the wires to a broadcasting station, the radio fans should begin to realize the immense sums of money being expended for their entertainment, and given to them without charge.

As for entertainment and general educational material, practically every program every day will be found to contain more text on subjects near to the home than any two home magazines. Moreover the facts are freshly gathered and as a rule are presented in a manner that cannot be approached by cold type and lifeless illustrations.

If the people of this country could be made to realize what they are missing during these fall days and nights, radio manufacturers would be forced to overtime work to fill the demand for better class receiving sets.

Let Radio World Test Your Goods

MANUFACTURERS, send a sample of your goods to our Technical Editor, Fred Charles Ehlert, 9006 Pleasant Street, Queens, Long Island, New York. It will be carefully tested. If your goods satisfy our experts, RADIO WORLD'S endorsement will be published in our merchandise department without charge or obligation of any kind on your part. When the radio purchaser sees a published test in RADIO WORLD with the seal accompanying this editorial attached, he will know that the product stands for perfection and has the guarantee of RADIO WORLD. RADIO WORLD is rendering a service through its testing department that is prompt, accurate and produces results. All goods will be returned to manufacturers, after testing, provided stamps are sent for that purpose.

Heard at Radio Counter

A Conversation Between Customer and Radio Clerk

(Part VI)

IN building a radio-frequency amplifier, should the panel be shielded for body-capacity effects?"

"In either radio-frequency or audio-frequency amplification, body-capacity effects will be eliminated if the panel is shielded."

"Then you really believe that in an unshielded receiver using radio frequency, there is a loss due to the set being improperly constructed?"

"Absolutely. In every case, shield your panel."

"Can I connect my output from the three-stage radio-frequency amplifier to the input of the audio two-stage amplifier with a detector?"

"Yes. This can be done very nicely and easily with a little patience. Watch carefully each connection you make, taking care of the proper plate-voltages. Another thing: don't forget to use all amplifying vacuum-tubes outside the detector. In this case, of course, we have to use the soft tube, better known to the layman as the detector tube. This, then, will give five amplifying tubes and one detector tube."

"Will my outside antenna work best with such a set; or must I employ a loop aerial?"

"Employ the loop aerial by all means and avoid using the outdoor aerial. The reason for the loop aerial is elimination of interference from stations, making the loop a practical compass-loop and cutting down static as well as interference."

(To Be Continued)

Coming Events

The editors of RADIO WORLD will gladly publish news items of all contemplated radio shows and expositions. Keep us posted by mailing full information.

SECOND NATIONAL RADIO EXPOSITION, direction International Trade Exposition Co., Chicago, January 13 to 20, inclusive, 1923, George A. King, director of publicity, 417 South Dearborn Street, Chicago, Ill.

PERMANENT RADIO FAIR FOR BUYERS, Hotel Imperial, New York City. Open from September, 1922, to May, 1923.

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, December 21 to 31. Colwell & Korbell, Fisk Building, New York City, directors of publicity.

SOUTHEASTERN RADIO EXPOSITION, Auditorium Armory, Atlanta, Georgia, December 4 to 9, inclusive. Co-operative Radio Sales Assn., 205 Peachtree St.

SECOND DISTRICT RADIO CONVENTION, Hotel Pennsylvania, New York City, March 1, 2, and 3, 1923.

A Valuable Book

THE third edition of the "Amateur Radio Call Book" has been issued by the publishers, Radio Directory & Publishing Company, 42 Vesey Street, New York City. It contains a complete list of all amateur, special amateur, and telephone broadcasting stations of the United States and Canada, also a large map in two colors showing the location of every broadcasting station. In addition, it contains valuable information on the construction and operation of a honeycomb-coil set, detector and two-stage amplifier. The book is divided into districts in the United States and Canada. The editor and compiler is Walter B. Spiegel, member of A. R. R. L., and H. R. C.

Every fan and amateur, particularly the DX night owls, will find this a valuable book. It contains just the information such radioists are constantly seeking. Price \$1, complete.

New Firms and Corporations

(The firms and corporations mentioned in these columns can be reached by communicating with the attorneys, whose addresses are given whenever possible.)

A. Schochet, Bronx, phonographs and radio sets, \$40,000; A. Schochet, A. Mintz, D. Lerman. (Attorney, P. Lerman, 110 West 42d St., New York, N. Y.)

CAPITAL INCREASE

The Orange and Rockland Electric Co. has increased its capital from \$1,000,000 to \$6,000,000.

Selling Radio to Farmers

IT is said that the farmers did a great deal toward making Henry Ford. They purchased automobiles because the automobile was a convenience that brought the city to their back door, says "The Mail," New York.

Who in radio is going to sell the farmer radio receivers? It is high time that such a campaign started. The rural territory is a potential one. Some business genius is going to hit upon the right plan for selling the farmers, and when he does he is going to make a fortune in a very short time.

Radio can be made indispensable to the farmer. This was proven by a recent case in Pennsylvania. A peculiar form of worm found its way into the corn fields. It was bringing about great destruction in certain localities. Experts of the Department of Agriculture got on the job and used the broadcasting stations of that State to tell the farmers how to effectively eliminate this pest. Great speed was essential; a delay of a day or two would wreck a large crop. The farmers who had receiving sets were out in their fields the next morning, applying the remedy that had been broadcast.

Broadcasting can be made so important to the farmer that the business angle of it should be handled by the various States working through the Department of Agriculture. A State owned and operated broadcasting station used to disseminate not only the information regarding market conditions, but practical talks on scientific farming would be a very good investment, costing only a small amount and bringing a large return. If a farmer loses a crop it may cost him anywhere from seven to eight thousand dollars. The State loses a certain amount of income, not only through tax but through general financial welfare.

Latest Radio Patents

To Receive a Plurality of Signals

No. 1,435,000. Patented, November 7, 1922. Patents: Edward W. Kellogg and Chester W. Rice, Schemectady, N. Y.

MESSRS. KELLOGG and Rice have been granted letters patent on a device to provide a method of and means for utilizing an antenna for the simultaneous reception of a plurality of signals of different wave lengths. With a long receiving-antenna extending in the general direction of transmission of the signaling waves to be received, signaling currents produced in the antenna by waves coming from any particular transmitting station will be strongest at the end of the antenna farthest from the transmitting station, while currents produced by waves coming from the opposite direction will be a minimum at that point. The antenna is preferably aperiodic, so that the strength of the signaling currents produced therein is substantially independent of the wave length.

In carrying out their invention, Messrs. Kellogg and Rice utilize an antenna of this type and impress from the antenna upon the input circuits of a plurality of electron-discharge amplifiers potentials produced in the antenna at a selected point. In order to improve the recep-

Schematic design of the Kellogg-Rice receiver.

tion, they also provide means for impressing on each of these input circuits a current selected from another point in the antenna which will be of the proper intensity and phase to neutralize in each

receiving set, disturbing currents produced therein either by interference from undesired waves or by strays. Each of the output circuits of the amplifiers employs a resonant circuit which is tuned to the frequency of one of the desired signaling waves, and these resonant circuits are associated with receiving sets.

Low-Priced Condenser

No. 1,443,244. Patented, October 24, 1922. Patented John Parkin, Jr., San Rafael, California.

OWING to the number of persons at present experimenting in radio signaling, there is a great demand for a variable condenser of simple construction and capable of being made and sold at a low price. Mr.

Vertical section and rear elevation.

Parkin's invention is to provide a variable condenser to supply this demand, and in which the elements are reduced to the least possible number and are of the greatest possible simplicity.

The Truth Will Bear Repeating

CHAS. FRESHMAN COMPANY

Incorporated
97 Beekman Street
New York City

November 7th, 1922.

Radio World,
1493 Broadway, New York, N. Y.

Gentlemen:—We wish to thank you for your successful effort in getting additional advertising copy on our Variable Grid Leak and Micon Condenser in your publication to appear in the issue of Saturday, November 11th, 1922.

The reason that we sent you the copy at such a late date was that it has been our policy to advertise only one of our various products in each magazine, and we had an advertisement running on our Noiseless Tested Micon Condenser for your coming issue.

The results that we obtained from our first advertisement of the Variable Grid Leak and Micon Condenser combined were so great that we did not want to miss the opportunity of having it re-appear in the current issue.

It might interest you to know that outside of the general publicity that our Variable Grid Leak and Micon Condenser combined received from the first advertisement in your publication that we have received hundreds of direct orders from individuals and payments enclosed mentioning the fact that they saw the advertisement in RADIO WORLD. These inquiries came from all sections of the country.

We wish to congratulate you on the exceptional distribution of your publication.

Yours very truly,

CHAS. FRESHMAN COMPANY, INC.

(Signed) Myron Goldsoll

Vice-President in Charge of Sales

Erecting SPC, Brazil
On the Summit of Mt. Corcovado, It Is
the Highest in the World

By Patriak Nichols

ENTERING the beautiful city of Rio de Janeiro the most impressive sight is the exquisite mountainous background of the city, and particularly Corcovado, an almost perpendicular mountain, with its summit over 2,000 feet above sea level.

"Why erect radio masts when such a mountain is so near by?" queried the Westinghouse engineers who journeyed there to erect broadcasting station SPC.

"Can we get the location?" This question was answered in the affirmative by F. A. Huntress, General Manager of the Tramway Light & Power Company, who own the cog-wheel railway that climbs Corcovado. He also stated, "We can supply 120-volt or 220-volt, 50 cycles alternating current on the mountain top for the radio outfit."

The party set out to explore the mountain crest. The first 2,000 feet of ascent, or five mile ride from Rio de Janeiro, was made in 30 minutes, and the final climb of 125 feet by following the foot path to the circular observation tower on the top.

A quick survey of the available space on the crest disclosed a narrow path about 125 feet long, leading to a concrete parapet on the edge of the precipice.

The crest of Corcovado had always been used as an observation point, but the radio-telephone engineers saw more than mere scenery—they had a view of the prospective invisible radio audience.

Two 125-foot masts were erected on the verge of the precipice on which are stretched a 153-foot six-wire antenna between two 26-foot spreaders. The counterpoise consists of two sections of five wires each, mounted on two 26-foot spreaders which are balanced on the ends of the 70-foot horizontal pole bolted fast to the mast on the summit. The counterpoise wires are stretched clear of the mountain sides, down about 100 feet to the tops of two poles located near the terminal building of the railway where the wires converging symmetrically form a 10-wire cage which leads into the radio telephone operating room. The hum of the 220-volt alternating-current motor was eliminated by a filter system made up of microfoid condensers and large choke coils.

A single-wire antenna was strung from the mountain top to the operating room about 125 feet below, for receiving messages. A speech amplifier is located in the operating room.

The call letters, SPC, were assigned. SPC has a unique position in the radio-telephony broadcasting field. At various times the station and antennae are in or above the clouds. Rio de Janeiro is practically on the boundary line between the Temperate and Torrid Zones. The climate is varied by the mountain range Serra do Mar which runs along the coast. The dry season will soon change to the warm and wet season and its subsequent tropical storms. Precautions are being taken to prevent electrical interference.

The observances and records of SPC will, therefore, assist in studying the peculiarities of the air as far as radio-telephony is concerned. The experiences of this station in penetrating the Equator and the Torrid Zone, when correlated with the data being compiled by other stations and close students of the new science, will no doubt result in listing peculiarities of the atmosphere unknown to science to-day.

"HOLIDAY RADIO GIFTS NUMBER" of RADIO WORLD will be issued December 9. Last copy will be accepted on this number up to November 30. RADIO WORLD, 1493 Broadway, New York.

DICTOGRAPH Radio HEADSET

Was \$12.00 **NOW** →

A sweeping cut of \$4.00 in the price of the Dictograph Radio Headset! The tremendous endorsement of radio enthusiasts has made possible this sensational reduction. To meet the demand, production has been planned on a new, gigantic scale. Great manufacturing economies establish the new price—only \$8.00.

A wonderful bargain! And above all, a wonderful headset—the world's standard of supreme quality for super-sensitive and accurate sound-transmission.

The same quality, the same guarantee, the same supreme Dictograph headset that has always sold for \$12.00, in every respect but the price. Type R-1, 3,000 ohms, for all types of receiving sets.

THE STANDARD OF THE WORLD

DICTOGRAPH Radio LOUD SPEAKER

The Perfect Loud Speaker for the Home

Public demand has made possible the Dictograph Loud Speaker at the low price of only \$20.00, complete with 5 ft. flexible cord. A handsome instrument that reproduces every sound in crystal-clear, natural tones, full volume, and free from distortion or noise. Ask for demonstration at reliable radio dealers. Get world-famous DICTOGRAPH quality and still save money.

Dealers: Order through your jobber or write direct for names of authorized distributors.

Radio Rates from Italy
OFFICIAL reports of new lines of radio communication between Italy and the United States, following the recent suspension of direct radio communication and pending the completion of a new high-power station at Rome, have been made to Washington by Commercial Attache MacLean, at Rome.

Radio traffic from Italy for the Western Hemisphere is now being handled by the high-power stations of Germany, France, and England, according to statements of the Ministry of Posts and Telegraphs at Rome. Full-rate and deferred messages, and press telegrams may be sent by Nauen Transradio and Radio-France, and full-rate and deferred messages by London Marconi.

Messages sent by Nauen are transmitted by radio from Rome and relayed at Nauen. Traffic handled by France or England is sent by land wires from Italy and thence by radio. Messages by France or Germany will carry a rate of twenty centimes, gold, less than the cable rate, in the case of full-rate telegrams. By London, the same messages would be ten centimes, gold, less than the cable rate. Deferred dispatches will be charged half the above rates. Press reports may be sent by France or Germany at the same rate as deferred messages, but will not be handled by London.

Two Danish Radio Clubs
TWO radio clubs, organized and supported by some of the most prominent figures in the Danish field of communications, have recently been formed to promote interest in radiotelegraphy and radiotelephony throughout Denmark. The aim of these clubs is to spread knowledge and create interest in wireless communication through lectures, demonstrations, and other means.

Broadcasting in Brazil

Centennial Celebration Stirred Up Interest and Promising Market for Receiving Sets Is Predicted

CONSUL General Alphonse Gaulin, Rio de Janeiro, reports to the Department of Commerce that preliminary steps have been taken for the introducing of radio broadcasting in Brazil, that indications point to a promising future market for receiving apparatus. Until recently radio broadcasting was practically unknown, but the Centennial Celebration being held at Rio de Janeiro has served to stimulate interest in radio and various concerns in Brazil have been active in taking it up.

The Rio de Janeiro Light and Power Company has recently finished a broadcasting station on the heights of Corcovada, using a wave length of 483. Music from the Municipal Theatre is sent to Corcovada summit by telephone and after amplification is sent out by radio. A studio near the summit also furnishes concerts and other entertainments which are heard locally. Additional broadcasting stations are now located at Monroe Palace (Congressional Building) and at the offices of the Marconi Wireless Telegraph Company. A number of receiving sets have been installed in the exposition buildings.

Imports of wireless apparatus have been received both from the United States and Germany for sale during the exposition. The requirements of the Brazilian law, however, make it obligatory for any person wishing to install a receiving set to secure a special permit from the Department of Transportation and Public Works. Only such receiving sets as have been approved may be sold by importers especially licensed to make such sales. The restriction and that limiting the sale to persons who have received a license to install and use wireless apparatus have hindered the exploitation of this important product. It is hoped, however, that by the beginning of the year a more definite policy will be established by the Brazilian Government and the markets for radio apparatus thrown open to importers.

A Broadcasting Problem

Should Manufacturers Contribute to Stations Sending Out Programs? Asks Bel Canto Corporation

EDITOR, RADIO WORLD:—Broadcasting has been under discussion for some time and much has been said pro and con; but I have something to say which I think is of paramount importance.

The Radio Corporation of America was the pioneer in broadcasting radio concerts and has not only kept up the fine quality of these concerts but has improved on them from time to time, giving radio fans the best quality of talent procurable. Without this broadcasting, there would be practically no market for radio parts,

and it is my opinion that each and every manufacturer of radio parts—whether it be a loud-speaker, a complete set, a hundred feet of antenna wire, or any of the other numerous parts that go into the making of a complete set—should be willing to contribute a certain portion of his net profits towards the maintenance of such a station.

Each and every manufacturer of radio parts is indebted to the broadcasting stations. Without them the manufacturer might just as well put the key in the door and hang up a sign, "TO LET." Why should a corporation, such as the Radio Corporation of America, spending millions of dollars to make radio a permanent, sound and healthy institution, which in time is destined to become one of the greatest industries of the world; or, in fact, any other organization maintaining broadcasting stations throughout the United States, bear the entire expense of maintaining these stations?

A certain percentage of the net profits of all the manufacturers, in my opinion, should be set aside to be paid over to the proper organizations conducting broadcasting stations throughout the United States, and that all unnecessary broadcasting of concerts, lectures, etc., should be abandoned. There is no necessity of having numerous broadcasting stations in one vicinity, for it only causes interference, which the average radio fan cannot tune out.

Proper broadcasting is the only thing that can make radio a real success; and I say again that each and every manufacturer who is now conducting a profitable business owes every cent of profit he is making to broadcasting. We are willing, ourselves, to set aside a certain portion of our profits for the purpose above mentioned. We feel that all other manufacturers will be in accord when they give it due consideration.—Duryea Benschel, secretary-treasurer, Bel-Canto Corporation, 417 East 34th Street, New York, N. Y.

Broadcast Bill's Radiolays

By William E. Douglass

THERE ain't no use in talkin', I've had troubles of my own, an' lately they've been pilin' in, they never come alone. First off I lost my chickens, dern near all died with the pip, an' then my dog keeled over without lettin' out a yip. The bay mare's got a collar-sore from plowin' here this fall; the other one is spavin'd—luck's deserted me, that's all. On Sunday I got all dolled up to take

Min in to church, an' when I cranked our Lizzy, she just up an' gives a lurch, an' knocks me down, blacks both my eyes an' tears my Sunday pants. Sometimes a flivver's pesky if you give 'em half a chance. I called old Lizzy some hard names, not knowin' why or which; to even up, on our way in, she runs off in the ditch. We got to church in time to hear our friend the parson say, "— give thanks for the blessings Providence may send your way." When old misfor-

tune comes my way, she does the thing up brown, but all the same it takes a heap to keep my spirits down. I've noticed too, most every cloud that dims our path so bright, has got a silver lining an' most things work out all right. Just last week, for example, Min got out my winter suit, an' found that it was stained a bit with plums and other fruit. She worked with it for quite a while an' got it good an' clean, I guess she must have used about two quarts of gasoline. Then in the kitchen by the stove, she hung it up to dry—the "Hook and Ladder" boys will tell you now I'm one suit shy. Likewise the house where I was born ain't what it used to be, we're shy about eight rooms or so, as far as I can see. We saved 'bout all the furniture an' grand-ma's feather bed, the only thing she thought of, though, was that there fancy spread that won first prize four years ago down at the Country Fair, an' after she had got it out she didn't seem to care a rap about the other stuff. But, like I said before, though trials and tribulations congregate about my door, there's bound to be a rosy side. My trouble's I'll forget, because I rescued first of all my good ol' wireless set.

—Copyright, 1922, Westinghouse Electric & Manufacturing Company.

Radio Don'ts

- DON'T** transmit without a government license. Don't be careless about your set.
- Don't let the aerial wires touch roofs, buildings, or trees.
- Don't purchase cheap apparatus and expect long-distance results.
- Don't place too many wires in your aerial.
- Don't forget that just as much tuning is required in the secondary as in the primary.
- Don't blame the set on poor reception. Sometimes it is improper tuning due to your own fault.
- Don't light the filaments to exceptional brilliancy and expect loud signals.
- Don't monkey with the works of your set if something goes wrong. Take it to an expert radio-dealer.
- Don't keep on changing connections if signals have been heard at their best. Leave well enough alone.

That Armstrong Circuit

So much interest has been displayed in the special article, "TESTED INVENTION OF MAJOR ARMSTRONG AMPLIFIES SET 100,000 TIMES," by John Kent, that appeared in RADIO WORLD No. 13, dated June 24, 1922, the publisher decided to put aside a number of copies for those who were not able to get this issue when published. Copies will be sent, postpaid, on receipt of 15c, or send in your subscription, \$6.00, for one year (52 issues), \$3.00 six months, or \$1.50 three months, and subscription will be started with the issue containing the article about Major Armstrong's Amplifier.—RADIO WORLD, 1493 Broadway.

YOUR NEWSDEALER

will deliver RADIO WORLD to your home. In order to be sure of getting RADIO WORLD regularly, and of not missing a single issue, we suggest that you either subscribe direct or through your newsdealer at \$6.00 a year (52 issues), \$3.00 six months, and \$1.50 three months. Or instruct your newsdealer to deliver RADIO WORLD regularly to your home each week. Dealers will take standing orders and make deliveries of paper whenever requested. Radio World, 1493 Broadway, New York.

Talk by Radio from Coal-Mine Depths

British Colliery Tests Prove Successful and Valuable Data Are Obtained

INTERESTING results were obtained by experimenters at the Baggeridge Colliery in Birmingham, England, a few days ago, says "Wireless World." Efforts were made to transmit messages from a depth of 700 yards to the surface. A three-tube set was used. The aerial was erected by slinging a wire from a steel hoisting gear 100 feet high to a girder of a railway bridge.

The ground wire was clamped to the lower part of a railroad rail. At first the transmitter and its aerial were installed in the steel cage, but considerable screening effect was experienced.

Tests were made at various distances down the shaft, and reception was found to be clearer when transmission was made at the lower points. This was thought to be due to presence of structural steel-work, which might have caused screening higher up.

Another experiment was made by taking the transmitter along the workings and groundings were effected by bringing a length of cable along the floor. The aerial was slung between pit props. Signals were clearly received at the pit mouth, although, owing to limited power of the transmitter, telephony was weak. It was suggested that the carbon in suspension in the air was having an absorbing effect on the signals.

Likes Mr. Miller's Set

Result of Trying Out Hook-Up in Radio World, No. 30, dated October 21

EDITOR, RADIO WORLD:—We have been trying out Mr. Miller's H-C hook-up the last few nights and using a U-V-200, but only have been able to get, in less than an hour's time, 2X1, WGY, WSB, and WDAP.

We find, however, that the tuning is extremely sharp and can be materially helped by using an .0008 variable with vernier and a vernier rheostat.

Last night (November 17), we tried out with two stages of amplification and a Western Electric power-amplifier with horn, with excellent results.

It's just about the simplest hook-up we have tried and, while critical, anyone should be able to work it.

In receiving code, however, we do not seem to get the proper increase of signal from amplification when using large coils for high-wave length.

We regard this hook-up as a good winter-time one; that is, for good radio weather, but doubt if it would be as satisfactory in summer time or poor radio weather. This would apply only to long-distance phone broadcasting.

It will also be noted that this hook-up treads on the toes of Major Armstrong.—Smith Novotoy Electric, Inc., Charlotte, North Carolina.

Air Service Radio School

A NEW Army radio school for training Air Service radio operators and electricians has been established at Chanut Field, Illinois. The school was recently removed from Post Field, Oklahoma, and new classes for radio instruction are being formed. Enlistments for training in radio for the Army Air Service are now being accepted at Chanut Field, where a six months' course will soon be started.

By Radio Across the Atlantic

How the New Langmuir Tubes Will Send the Human Voice in Both Directions

SENDING radio messages across the ocean by means of the tubes presented a contrast of apparatus. The Alexanderson alternators almost fill the center of the Rocky Point, Long Island, plant, whereas the tubes to be used, invented by Dr. Irving Langmuir, of the General Electric Company, Schenectady, New York, could be put in a suit case.

This does not mean that the alternators will be immediately superseded, because the tubes' superiority has not yet been sufficiently demonstrated to permit the scrapping of the larger machines, although the eventual adoption of the tubes is considered inevitable. Their value, says "The Times," New York, will be even greater to wireless telephone development, than to telegraph efficiency, as they were evolved by application of the same principle that has made the audion tube the most important achievement of those working on the wireless telephone.

The human voice already has been carried across the Atlantic by wireless, but only in one direction. By means of these electron tubes it is expected that the voice may be sent both ways without difficulty, so that extended conversations may be carried on. This is not exactly the same as two voices talking at once, as wireless communication is made at the speed of light and a word would reach Paris from New York so quickly that there would be no interference with the word coming back.

Plans for the development of the new electron tube experimental set were completed in December, 1921, by representatives of the research and engineering departments of the General Electric Company and the Radio Corporation, and the manufacturing of this highly delicate and specialized set was immediately started in Schenectady, New York. So fast did the work progress that in May of this year the temporary installation of the set was started at Radio Central, the Rocky Point station, and when Marconi visited the station in July preliminary tests were in progress under the direction of W. R. C. Baker of the General Electric and C. W. Hansell of the Radio Corporation.

The set at present consists of three fifty-kilowatt, 15,000-volt, water-cooled, metal vacuum tubes, known in the engineering world as kenetrons, and used as rectifiers; and six 15,000-volt, twenty-kilowatt, water-cooled metal plotrons, used as high-frequency converters. For the experiment with the tube set one of the new mile-and-a-half-long antennae, suspended from six towers, 420 feet high, was used, and the tube set succeeded in developing and sustaining in the antenna a current of the strength of 350 amperes. About 600 amperes has been used with the Alexanderson alternators, but it has been found that with the development of wireless apparatus a lower amperage may be used.

The most interesting feature about the experiment to the engineers conducting it was that the receivers and senders did not know that the change from alternators to tubes had taken place. There is little difference in the tone, the tube tone having a sort of companion wave sound, a kind of wireless echo, which, however, proved to

be almost indistinguishable until it was pointed out to the receiver. The switch from alternators to tubes was made without notifying the senders or receivers at 64 Broad Street, and although the man receiving messages from abroad sits on the other side of a table from the man sending, the receiver did not notice the change in the New York plant signals.

THE ONLY GENUINE AND GUARANTEED

"All Wave" Coupler

TRADE MARK

(FLAT AND BANK WOUND) Wave Length, 150 to 3,000 meters.

Eliminates the use of all Variometers, Variocouplers and Loading Coils, inasmuch as it performs in one compact unit the functions of all of these devices combined.

For the Novice—The six efficient hook-ups given free with each "All Wave" Coupler enable the greenest novice to attain the same results attained by the expert in building the simplest, most compact and most efficient radio receiving set possible.

Be Prepared—For the higher wave lengths that have been and will be allotted to broadcasting stations because of their ever-increasing number. BUILD a set that cannot become obsolete.

Unusual Results Attained—Individual users of the "All Wave" Coupler have written us that in New Jersey they have listened in as far west as the University of Wisconsin and Chicago, whereas in Montreal, Canada, it is nothing unusual to bring in Schenectady, Detroit, Chicago, Pittsburgh, Newark and the Arlington time signals, direct, and in Mobile, Ala., Newark, N. J., is brought in daily.

Beware of Imitations—of the "All Wave" Coupler, which is guaranteed with a money back to operate as advertised. Look for the trademark, "All Wave," on the rotor, also the six efficient hook-ups in the box.

\$9.00 Six efficient Hook-ups sent upon receipt of 10c. stamps or Free with each "All Wave" Coupler

GUARANTEED WITH AN ABSOLUTE MONEY-BACK GUARANTEE

WE NEED RADIO WORLD, dated April 23 and August 5. If you have copies you don't require, mail to this office and current issues will be sent you for them. RADIO WORLD, 1493 Broadway, New York.

Are you familiar with all the radio symbols used in the various hook-ups published in Radio World? If not, secure a copy of Radio World No. 26, dated Sept. 23. In this issue was a complete table of all important symbols used in radio construction and testing. Send 15 cents for a copy, or \$6.00 per year, and have subscription start with that issue. RADIO WORLD, 1493 Broadway, New York City, N. Y.

at most twice in the year—on Christmas and on the Fourth of July. For months together you are shut out from all physical contact with what we ordinarily speak of as "the world." No newspapers, no letters, no rumors even of what is going on a hundred miles away.

And then imagine that someone installs a radio outfit, so that you can listen nightly to the news of what is happening all over the world, and to concerts and lectures. You are no longer isolated. You are up to the minute in your knowledge of affairs.

This is just what has happened in many lumber communities. Away out in the forests of the Coast Range in Oregon and Washington, the Hammond Lumber Company has installed powerful receiving sets in more than twenty of the logging camps. The lumberjacks listen in on San Francisco and Portland and Seattle, and never lack for entertainment.

A highly interesting feature of the installation of these radio-receiving sets is the preparation of a pair of poles to support the antenna wire. Trees about 300 feet high and, perhaps, six or seven feet in diameter are selected. The lumberjack, with the aid of a rope and a pair of climbing irons, runs up one of these trees like a squirrel, lopping off the limbs on every side until the tree is like

a telegraph pole. Then a wire, perhaps a thousand feet long, is strung between two trees at a great elevation. A lead-in wire connects with the radio apparatus in tent or cabin; and after tuning difficulties are overcome, everything is in readiness to receive messages.

At Your Service!

There appeared in RADIO WORLD, dated April 1, 15, and 29, the following articles.

April 1—A 500-Mile Radiophone Employing a 5-Watt Tube, by Frank A. Hahnel. "Tell Me, Please, How Will This Set Receive?" by E. L. Bragdon. Short Cuts in Receiver-Circuit Design, by O. C. Roos. Making a Short-Wave Regenerator, by Fred. Chas. Ehler.

April 15—First Principles of Electricity as Applied to Radio, by John P. Miles. Your Storage Battery, by E. L. Bragdon. What Makes Radio Possible, by Edward Linwood. Ground Connection as Vital as Antenna, by Fred. Chas. Ehler.

April 29—Valuable Pointers on Aerial Construction, by Edward Linwood. What Is Meant by Tuning, by E. L. Bragdon. Radio-Frequency Amplification and Regeneration, by Frank Armstrong. Honey-Comb Coils and Condensers, by Edward Linwood. Charging the Storage Battery, by E. L. Bragdon. How to Construct the Variocoupler, by Frederick I. Rumford.

Each copy sent on receipt of 15c. per copy, or the three copies for 45c.; or better still, send your subscription beginning with any one of these numbers, and we will send this paper for 52 issues, and you will then have a complete file for ready and constant reference. RADIO WORLD, 1493 Broadway, New York.

Functions on an Antenna at Any Wave-
Length, Declares the Inventor,
Dr. B. G. McCaa.

PREVENTION of static interference in radio reception has been solved, according to Dr. B. G. McCaa, of Ephrata, Pennsylvania. Dr. McCaa, who has been working on static problems for over four years, is not a doctor of radio or any other science, but a "simple M. D.," he says. He took up X-ray and high-frequency work in medicine and became a radio "bug" ten years ago. In a communication to RADIO WORLD, he describes his invention for the killing of static as follows:

"The antistatic work was taken up early in 1918, and, in the course of four and a half years of search and testing, three systems only, out of many studied, have shown any merit. Let us designate them as A, B, and C.

"During July of this year, tests were made of systems A and B, in combination, on the commercial-telegraph channels of the Federal Telegraph Company in California. Repeated observations made by many engineers showed signal to static ratios of 200 to 1. Static of 3,000 to 6,000 times audibility was reduced to audibilities of 10 to 50, and signals 200 to 250 times the strength of the static received at the same time.

"System A reduced static to a one-to-one ratio, and system B improved the ratio as given above.

"From the practical result, i. e., readability of signals, operators could take solid copy on 'stuff' that could not be copied on standard receivers.

"System C is a more recent development and replaces system A, as it has proven far superior to A in many respects. Combining C and B, absolutely static-free signals have been obtained in the presence of nearby electrical storms.

"All the systems are designed to function on an antenna and do not depend for their operation on the vagaries of directional propagation or some mysterious 'origin' of static. They may be used on closed coil or loop reception as well as on ground or water wires.

"Systems A and B in combination are adapted solely to radiotelegraphy and may be used at any wave-length.

"System C operates at any wave-length and possesses the decided advantage of being applicable to radiophone work at any wave-length. It has been proved to function at 360 meters. The device is simple; it has but one adjustment, which, when made, remains fixed for all time like any other tuning adjustment."

Radio Goods Active

HOLIDAY business is taking on more life in electrical goods and some cities report shortages of certain stocks of heaters and ironers. "Electrical World" will say tomorrow: "Central station activity in making line extensions is taking much high tension equipment. Motors in all sizes are moving well."

Radio jobbers report better sales, saying that a lot of the business is going to parts and head sets. Vacuum cleaners are also in demand and washers are more active. The mild weather and improvement in the coal situation has slowed down the sales of heaters but purchases are frequent.—"The World."

UNION-RADIO PHONE TIP JACKS

(Patent Applied For)

FRONT (Outside) VIEW

They are valuable wherever head phones are to be used. Especially convenient in connection with CW circuits. Countless uses have been found for them.

The use of binding posts to connect phone tips has always been unsatisfactory. It is difficult to keep the tips from falling out of the binding posts.

These Union Radio Jacks will accommodate any telephone cord-tips manufactured. To mount them on any panel, just drill a hole, using a

7/64 drill, insert the bushing, and screw on the lock nut which holds the combination tension spring and soldering lug in place.

The tip when inserted is firmly held. And a good electrical connection is assured at all times. These Jacks eliminate the buying of an expensive telephone plug and Jack.

Ideal for experimental circuits or in any part of a set where quick changes are needed. They accommodate wire up to the thickness of telephone tips.

25c. A PAIR

We also manufacture complete receiving sets, 2 step amplifiers, variable condensers, receiving vacuum tube receptacles, condensite dials, etc. Our catalog M, "Radio Apparatus," sent on request.

Radio Now Used in the United States Congress

(C. International News Reel)

President Harding delivering his recent message to Congress. The bell-like apparatus suspended from the ceiling are microphones which catch his words for broadcasting. The square discs in front of the reporters are also microphones to catch their orders.

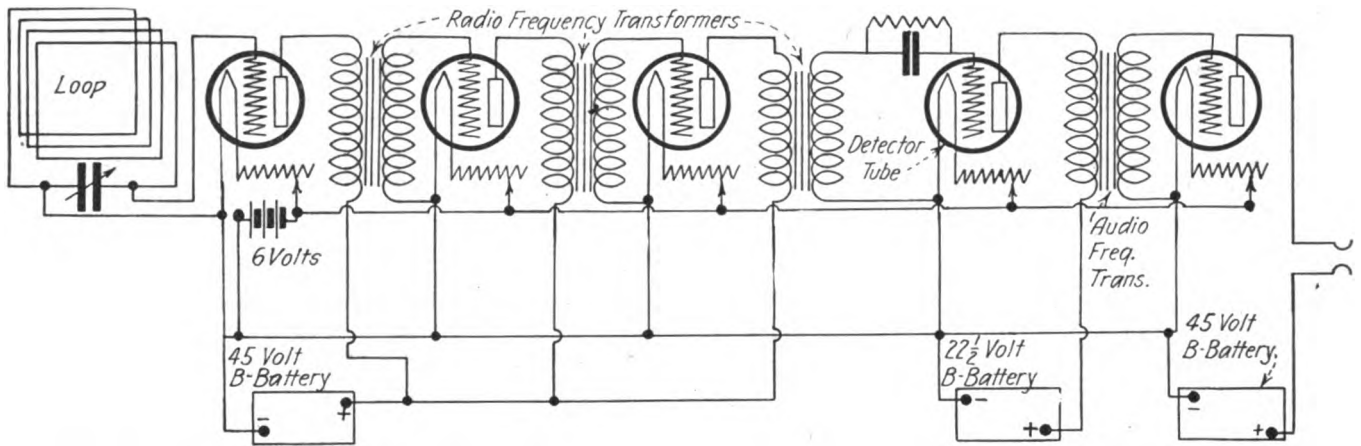

Figure 1—Schematic diagram of a five-tube radio-frequency receiver. The first three tubes and transformers are the radio-frequency amplifiers, the next tube is the detector, and the last tube is a one-stage of audio-frequency amplification. A loop aerial is used. Suggested by George W. May. Drawn by S. Newman.

Why Radio-Frequency Amplifies Signals

By Donald Van Wyck

RADIO-FREQUENCY amplifiers are attracting considerable attention. Radio fans who are unable to erect a satisfactory antenna may improve the strength of incoming concert music, or increase hearing range, by means of radio-frequency amplification, audio-frequency amplification, or a combination of both. In cases where the receiving station is near the transmitting station, the energy received is usually sufficient to reproduce sounds without radio-frequency amplification. When the receiving station is more remote, the signal must be built up, or amplified, before it passes through the detector and the stages of audio-amplification. If radio amplification is not used, audio-frequency amplification in such cases is frequently of little use. In the first place, the fundamental difference between radio-frequency and audio-frequency amplification is far from clear to many of the amateur operators of to-day. As the names imply, both instruments amplify the signals received from distant broadcasting stations; but they do it in a widely different manner. The audio-

frequency method, for instance, amplifies whatever the detector delivers to it and, therefore, increases the volume of sound in the head telephones. It is obvious that if a certain signal is too weak, by the time it reaches the receiving antenna to operate on the detector, no amount of audio-frequency amplification will make it audible in the head phones. Radio-frequency amplification, on the other hand, goes straight to the root of the trouble. The radio-frequency tubes precede the detector in the circuit and confine their work to the radio impulses in their original form. In accordance with the natural action of the vacuum tube, these impulses are successively strengthened by as many tubes as desired. When they are deemed sufficiently strong they are passed to the vacuum-tube detector for conversion into currents of audible frequency. Once audible sounds are produced, audio-frequency amplification may be relied on to obtain the desired volume.

The connection between the amplifying vacuum-tubes may be merely a wire or, possibly, a very high resistance; or it may be some form of a

transformer. The first method, that of a direct connection, is unsatisfactory and is never used in actual practice. The second is fair and has received more or less recognition. The third method of using transformers is the most satisfactory and is most generally used. The transformers may be of the air-core type or of the iron-core type, which has two independent coils known as primary and secondary, respectively, mounted on laminated legs. The iron-core amplifying transformers give the best results and, paradoxically, also give most trouble to the uninitiated.

The amount of iron in any transformer is dependent on the frequency of the current which is passed through the windings, and the higher the frequency the less the iron used. Since the iron must reverse its polarity with each reversal of the current, this indirect ratio may be explained easily.

With audio frequencies, such as are encountered in signals after they leave the detector, the design of the transformer is not difficult. But when it is remembered that the radio-frequency of a 200-meter wave runs into the millions of cycles per second, the complexity of the task which confronts the designer of radio-frequency amplifying transformers is realized at a glance.

The design of the radio-frequency amplifying transformer would not prove a thorn in the sides of the manufacturers if the commercial phase of the question could be side-stepped. It is not much of a problem to construct a transformer which will function very well in a narrow band of wave lengths: say from 200 to 300 meters. But such a device would not meet the sanction of most amateurs because they do not wish to be put to the task of changing transformers for the various wave lengths. Beware of all-wave radio-

Figure 2—Another schematic sketch of a radio-frequency receiver. This diagram shows two radio-frequency tubes and one detector-tube in operation. This circuit should produce unusual results on DX work. Suggested by George W. May. Drawn by S. Newman.

Capacitively Coupled Receiver for DX Work

By Arthur O. Curtis

CAPACITIVELY coupled circuits are those in which condensers are used to connect primary and secondary circuits. By varying their values, a set may be placed in tune with a transmitting station. This type of coupling is said to be electrostatic, since condensers function only by reason of their electrostatic field. A simple circuit shown accompanies this article. This diagram, when used with such a receiver, will operate successfully on short waves. It is seen that the primary circuit is essentially a parallel resonant circuit, as distinguished from the series of resonant circuits that are common to the direct and inductively coupled

circuits. Sharp tuning is accomplished more successfully with this type coupled affair than with any other, and it is somewhat more efficient than other types. Adjustments may be said to be more critical and, generally, there are more adjustments to be made with this type set than with any other. The

three variable condensers C, C1, and C2 are of .0005 micro-farad capacity. L1 is the primary inductance coil and L2 is the secondary inductance coil. The tuning is controlled by C2, while C and C1 act as the coupling control. The primary (which is L) consists of forty turns of No. 24 cotton-covered wire wound on a tube $3\frac{1}{2}$ inches in diameter. L1 has 30 turns of No. 22 cotton-covered magnet wire wound on a tube $3\frac{1}{2}$ inches in diameter. The coils, when in operation, should be placed at least four inches apart. The degree of coupling is determined by the amount of capacity of C and C1. Broad tuning can be had by increasing the capacity. Small capacity affords sharper tuning and minimizes interferences. The secondary coil in the detector circuit is of standard type and is used to obtain satisfactory results. Changing the capacity settings for these coupling condensers does not change the resonant frequency of the circuit, but merely changes the amount of energy transmitted from the primary to the secondary through the condensers.

Condensers may be used to a great advantage by employing a capacitively coupled receiver. The above schematic diagram shows such a circuit. The condensers act in this circuit as a coupling between the two coils. Drawn by Arthur O. Curtis.

(Continued from preceding page)
frequency transformers. They will not function. Several schemes have been tried for circumventing the natural limitations of the radio-frequency transformer. One has the division of the windings in sections with suitable taps brought to the surface. By means of either binding posts, or a movable contact-arm, the transformer is tuned to the particular band of wave lengths to be received, and, therefore, the loss incident to using a transformer designed for one frequency on a vastly different one is partially avoided. The other scheme provides a series of transformer units to be plugged in and out in accordance with the tuning.

The most common radio-frequency transformer on market resembles the audio-frequency type and is designed to function on a band of wave lengths from 200 meters to 450 meters.

Accompanying this article are two schematic diagrams of practical radio-frequency circuits which consist of three stages of radio-frequency and detector; also, one stage of audio amplification. For the antenna with this particular set, I used the loop aerial as explained by me in RADIO WORLD, No. 33, dated November 11. The loop aerial (Figure 1) gives the marked advantage of eliminating interference and practically makes a directive antenna a compass loop. The loop aerial will function satisfactorily if used with this three-stage amplifier. Figure 2 shows a two-stage amplifier of the radio-frequency type with vacuum-tube detector. Any one contemplating the building of this set will find that it works far better than some others.

Take Care of Your Storage Battery

(C. Kadel & Herbert, N. Y.)

The storage battery—these cells of electrical energy are of vast importance. Most of the receiving outfits, to-day, using vacuum tubes need such a storage battery. The storage battery is rather a delicate affair, even if it does weigh a lot. Care must be taken that it does not deteriorate quickly. With good care a battery for radio work should last several years. The above photograph shows how to keep a battery clean. A clean battery will prevent short circuits.

Efficient Crystal Set at Small Cost

By Charles H. Plath

Figure 1—Simple circuit with a slide tuner. This will receive phone reception up to a certain limit. Both sketches drawn by Charles H. Plath.

Figure 2—When taps are used, two switches are necessary in a circuit—one for the large steps of inductance and the other for the small steps.

WITH radio broadcasting becoming more popular, many people are willing to spend a small amount of money in order to break into the radio game. For such people, the crystal set still holds its own. There is practically no upkeep of expense as its cost is low. At any rate, those who break into the game, if it does nothing else it will turn the most disinterested radio prospect into a "bug." Radio waves are passing through and about us all the time. We cannot hear radio waves without the aid of instruments. No matter what type of apparatus one decides to purchase, it is worth while to purchase the parts, or units, that may be added to from time to time as one's interest increases.

For any type of receiver, we must have some sort of an aerial. My experience has taught me that, for receiving purposes only, nothing can equal a single-wire aerial about 75 or 100 feet long. This wire must be about No. 14 B and S gauge. When erecting it, insulators must be used to prevent the wire from losing its energy and, possibly, becoming grounded. Once it becomes grounded, all radio waves, or energy, will be grounded and no sounds will be heard. This mistake must be avoided, and a careful examination should be made when erecting the aerial. Insulators should be placed at all points where the wire may come in contact with some metallic, or conducting object, such as a metal roof, damp surfaces, and metal stays or guy wires. There should be provided also sufficient wire to reach from the instruments to the nearest cold-water pipe. Next secure a single-slide, or two-slide tuner. With this piece of apparatus you will be able to tune in the stations you desire up to 600 meters.

By adding a crystal you will have the simplest possible apparatus for reception. This is shown in Figure 1. A pair of phones, or a single phone, is a requisite for sets both large and small and care should be taken for selection. They should be rated at from 2000- to 3000-ohm phones. Phones should be of the best materials and most carefully made; therefore, if your means are limited it is better to buy a single phone of known quality.

Two sliders on the coil will produce greater selectivity. They operate similar to an autotransformer—the turns between the aerial slider and the ground end of the coil may be considered as the primary, and the turns from the ground end of the coil to the other slider may be considered as the secondary. A variable condenser may be connected across the coil to sharpen the tuning.

Still greater selectivity may be obtained by employing a loose coupler as shown in Figure 2. Here there are two circuits. They must be tuned to resonance with each other and the incoming wave. The circuit in which the aerial, ground, and one of the coils is connected is called the primary, or open cir-

cuit and the circuit that contains the detector and phones is called the secondary circuit, or closed circuit. This also takes in the other coil. Loose couplers are so constructed that the secondary may slide out of the primary. This relationship between the two coils is known as the degree of coupling.

Radio Is the Biggest Show on Earth

The performance: Complete grand operas, baseball and football—play by play; we can even hear the bat strike the ball, hear the crowd cheer. In an instant, we are at the ringside! There is a prize fight on. We can almost hear the knockout wallop—get the thrill of things as they happen. And, on Sunday, the entire service at one of the leading churches.

News, amusement, the most interesting things of the world, are brought instantly into our own home by radio.

Let every owner of a radio-receiving set who knows the joys of this, the greatest of all amusement devices, invite some friends into his home during National Radio Week, December 23 to 30, inclusive, and so bring joy and happiness into another's life during the joyous Christmas season. That's what Christmas is for—to bring happiness to others.

The object of National Radio Week is to double the number of radio fans. Let every radio enthusiast make it his business during this week to enthrone another—to bring a radio-receiving set into a home that now lacks the thrill of being in constant, instantaneous touch with the great actors on the world's stage.

A radio receiving-set costs less than a good phonograph; also, the upkeep is much less. There are no records to buy, nothing to wind up—and an entirely new program every hour.

Radio amuses and interests every member of the family with scientific lectures on psychology, to bedtime stories for the kiddies—grand opera to jazz—one gets what one likes the best. By the slightest turn of a dial, we turn in to the broadcaster that most interests us, for radio service and amusement, today, is almost unlimited.

Radio keeps a home together. It makes one's home the center of the universe.

A Christmas Thought for National Radio Week

THOUSANDS of readers of RADIO WORLD will be purchasing new radio sets or replenishing their present equipment between this date and Christmas Day. Why not share your joy of ownership by taking advantage of the special opportunity offered during National Radio Week and set aside one or two evenings during that week for the entertainment of less fortunate friends by letting them listen-in on your set?

National Radio Week is from December 23 to December 30, inclusive. Each reader of RADIO WORLD can help radio along its merry and interesting way by getting up a Radio Party and, by so doing, increase the ever-growing army of radio enthusiasts.

Remember, the National Radio Week dates are from December 23 to December 30. Make your plans in advance and then write and tell us, briefly, what you have accomplished to help make those closing days of December memorable in the history of radio in this country.

Radio, This Christmas of 1922

A YEAR ago, when radio had not progressed to its present high place in the world of science and entertainment, the question asked by everybody interested was: "What will the Christmas of 1922 bring forth? The proper results of reasonable development or merely the chaos that so often follows tremendous interest in something new?"

Well, the now holiday season is here and with it comes the answer.

Radio has justified itself both as a science and as the amusement of millions. Great changes have come. Scientists have given of their best in adding definite expression to the potentialities of radio. While formerly there was confusion as to certain technical angles there has come the solution of many difficulties. Where tens of thousands formerly were interested, millions now pay the tribute of earnest interest and enthusiastic attention to these solutions of problems that have been offered by some of the keenest minds in science.

TO be sure, there came an apparent lull in interest last summer. Merchandising conditions became confused. Static, that imp of the ether, took a hand in confusing the minds of many and adding to the difficulties of the great national sport, "listening in." These difficulties are being framed out. The business of manufacturing, distributing, and selling are becoming standardized as the demand becomes fixed and the business elements of radio better understand what is expected of them. Static trouble has been minimized by new inventions until, finally, it seems agreed that by next summer, this trouble may be compelled to hide its diminished head, and, perhaps, disappear entirely.

Radio has become something more than a fad. It is now one of the world's greatest natural utilities. Nations depend upon it for enlightenment and the interchange of diplomatic, scientific and business messages. Armies and navies, whether they continue to exist in a menacing or a protective measure, find radio an adjunct of marvelous power and usefulness. Great human problems of transmission are being solved through this wonderful agency. In fact, every activity of life, whether commercial, artistic, or even spiritual, is being affected in varying degrees by this new marvel. And so far as religion is concerned, people are listening to sermons who never listened to them before.

AS for the public itself, there is not the slightest doubt that radio has left a deep impression on the universal mind. Many millions, comprising the enthusiast with the "makings" and the owner of expensive receiving sets, all along the line to the modest listener-in who takes his place at the great guest board and is delighted by the wonders borne to his willing ears—all are steadfast admirers of the new science and help to swell the world-wide army of radioists.

And to the big broadcasters, those pioneers who bring the world into closer communion, who afford equal joy to the millions in crowded centers as well as those on the outposts of civilization, the thanks of the world are due. For, in the final analysis, it is to successful and ever-improving broadcasting that the whole craft must look for continued interest and consequently continued success.

—THE EDITOR.

What Leading Radioists Tell the World

Progress Due to Close Cooperation

By S. W. Stratton

Director, United States Bureau of Standards

THE past year has shown a remarkable development in the use of radio as a method of communication, especially in cases where the ordinary methods are not available.

This progress has been brought about by a close co-operation between manufacturers, commercial companies, amateurs and government officials. This problem has been a very difficult one owing to the nature of the principles involved and our lack of more definite knowledge in regard to them.

Scientific laboratories throughout the country have concentrated on these fundamental problems of radio; their contributions to the subject have been eagerly sought for and immediately applied, a fact which has been of vital importance in these astonishing developments.

A Message from New York's Police

By M. R. Brennan

Superintendent of Police Telegraph, Police Department of the City of New York

AS the Christmas of 1922 approaches the Police Department of the City of New York feels an especial pride in the fact that the public will be furnished with a service that will add to their protection by broadcasting police information for the apprehension of criminals and the recovery of stolen property. The Police Commissioner also expects to be able to furnish an entertainment program which will be highly instructive and enjoyable...

Earth Spanned by Radio Peace

By Alfred N. Goldsmith

Head of the Department of Electrical Engineering of the College of the City of New York

PEACE on an earth spanned by the radio waves carrying the message of good will from man to man.

Let Us Rejoice and Be Glad

By Lee de Forest

Inventor of Many Important Radio Devices

LET us rejoice and be glad in this idea of a Radio Christmas! Not only for this year but for all years to come! Indeed, why not? Not alone for the immediate joy that it will bring to the heart of the individual boy or girl. Not alone for the further encouragement it will bring to the men who are giving time and thought to the development of the industry itself; but for the greatest of all reasons: namely, that with the radio art we of the industry are installing the most marvelous of all

instruments for spreading the tidings of peace on earth and good will toward men.

Radio Has Come to Stay

By H. Gernsback
Editor "Radio News"

THERE have been many Christmas celebrations in which radio has played a part, during the past ten or twelve years, but this is really the first Radio Christmas. It is the first time that radio has penetrated into the homes of a very great proportion of the population of the United States, and for that reason it should be celebrated by every one interested in radio with this in mind. Radio has come to stay, and the writer trusts that it will be the means of bringing good will and cheer to every one connected with radio.

Broadcasting, a Public Utility

By Jack Binns

Radio Editor, "The Tribune," New York City

BROADCASTING is rapidly assuming the status of a public utility. Any plan which will foster its development along right lines is a contribution to human progress. The idea back of National Radio Week constitutes such a plan and, I hope, will materially aid in placing broadcasting where it rightfully belongs in the public esteem.

Awestruck at the Future

By Elmer E. Bucher

Manager, Sales Department, Radio Corporation of America

IF radio broadcasting accomplished nothing else, it would be well worth while for the splendid entertainment and contact with the outer world which it brings to the isolated community or individual and to the sick and the feeble. But already has this great facility demonstrated a hundred worthy uses, from the amusement of tots in their nurseries to the dissemination of important information to business men and farmers the country over. With such impetus as radio broadcasting has gathered in its short existence, even we in the industry are awestruck at the future possibilities of this institution in which we are workmen.

A Mighty "Yes," the Answer

By Charles E. Fay

Tufts College, Boston, Massachusetts

DOES not the marvelous invention of radio offer the best means devised since the first Christmas for broadcasting the message of "Peace, good will to men?"

The Aerial Press of America

By *Washington R. Service*

PERHAPS, at last, there is something new under the sun. Whoever thought of an aerial newspaper before a few pioneer mentors of public opinion began broadcasting their news items that all who "listened in" might hear—free?

Among 582 radio stations broadcasting in the United States, today, there are 83 representing publications—most of them daily newspapers. Nine of these etherial news sheets are super, or Class B, stations especially licensed to broadcast on a 400-meter wave. All told, these news broadcasts of the air reach millions who do not subscribe to the publications but who are most enthusiastic aerial "hearers" none the less loyal to their favorite papers because they are unknown to the editors. There is an "Aerial Press of America" even though there are no aerial subscription lists and no advertising accounts.

It is certainly something new, this broadcasting of the news and sports of the world, gratis. It is a service highly valued by the hearers. Many predict that it has come to stay. Some Canadian newspapers have also taken up the scheme of news broadcasting, as well as publications in Porto Rico and Hawaii.

George Schubel, secretary of the Radio Broadcasting Society of

America, a publisher, has made a study of aerial news distributing, with the result that he advocates the broadcasting of news matter by publishers. Paralleling the printed news, he claims, broadcasted news serves both national and local fields and provides for a versatility of free expression of public opinion. Radio can be used in the gathering of news as well as in its dissemination, especially in country districts, and tends to broaden the scope and circulation of a newspaper. There are several known instances where radio carried daily news reports when other lines of communication failed, and, in some instances, amateurs aided. An SOS story has been covered by wireless and aid rendered by means of radio as well on land as at sea. Instances where the wires and regular channels were beaten are recorded.

Government weather, crop and market reports are now carried by radio in advance of press releases. The only way by which a newspaper can hope to compete is through the same medium.

"Why give away material?" may be asked. This is answered by citing the case of the Boston "American's" experiments in broadcasting bulletins from its news before they were printed. The news is transmitted from WGI,

Medford Hillside, and the service to thousands is reported to have brought most valuable publicity to the Boston sheet. All who listen in to brief news items want to know more of the details and, naturally, purchase a copy of the "mother" sheet as soon as it is available. Out of over eighty papers licensed to broadcast, only about half a dozen have stopped this service. A few have combined with other organizations in the use of a single broadcasting-station.

The following United States newspapers operate broadcasting services:

KDYU—"Telegram," Salt Lake City, Utah.

KDYR—"Star-News," Pasadena, California.

KDYS—"Tribune," Great Falls, Montana.

KDYU—"Herald," Klamath Falls, Oregon.

KDYX—"Star-Bulletin," Honolulu, Hawaii.

KDZA—"Daily Star," Tucson, Arizona.

KDZH—"Evening Herald," Fresno, California.

KDZR—Bellingham Publishing Company, Bellingham, Washington.

KFAC—"Daily Press," Glendale, California.

KGW—Oregonian Publishing Company, Portland, Oregon.

KLX—"The Tribune," Oakland, California.

KSD—"Post-Dispatch," St. Louis, California.

KUO—"The Examiner," San Francisco, California.

KWH—"The Examiner," Los Angeles, California.

KXD—"The Herald," Modesto, California.

KZN—"Salt Lake Deseret News," Salt Lake City, Utah.

WAAF—Chicago Daily Drovers Journal, Chicago.

WAAL—"Tribune," Minneapolis, Ohio.

WBAD—"Journal," Minneapolis, Texas.

WBAT—"Star-Telegram," Fort Worth, Texas.

WBAU—"The Republican," Hamilton, Ohio.

WCAB—"The News," Newburgh, New York.

WCAG—"The States," New Orleans, Louisiana.

WCAW—"The Herald," Quincy, Massachusetts.

WCX—"Free Press," Detroit, Michigan.

WDAE—"The Times," Tampa, Florida.

WDAF—"Kansas City Star," Kansas City, Missouri.

WDAK—"The Courant," Hartford, Connecticut.

WDAL—"Times-Union," Jacksonville, Florida.

WDAV—"Muskogee Daily Phoenix," Phoenix, Arizona.

WEAR—"Baltimore American," Baltimore, Maryland.

WFL—"The Chronicle," Houston, Texas.

WFAM—"The Times," St. Cloud, Minnesota.

WFAT—"Sioux Falls Daily," Sioux Falls, South Dakota.

WFAW—"Daily Metropolis," Miami, Florida.

WGAR—"Fort Smith American," Fort Smith, Arkansas.

WGAZ—"The Tribune," South Bend, Indiana.

How to Prepare Hard Sheet-Rubber for Your Radio Apparatus

By *W. S. Standiford*

THE experimenter in all kinds of electrical apparatus finds it necessary to cut hard sheet-rubber into round discs for making Wims-hurst machines, or for parts of wireless-telegraph and telephone sets now used extensively. The amateur radio-telephone-maker uses wood for his panels and large diameter cardboard tubes for his vario-coupler, tuner and other parts.

While wood may be used for a panel, it is not nearly as effective as hard

rubber. Factory-made appliances are constructed of the latter or of an insulator equally as good. Cardboard is a fragile substance and does not give continuous service as a vario-coupler. On account of hard rubber, in its dry state, being difficult to cut and bend into cylinders for radio parts, amateurs use wood and cardboard. The writer, after some experimenting, found an easy way to cut and bend hard sheet-rubber 5/16 inch thick. Mark an outline on the place to be

cut, using a scribe or knife. Then plunge the sheet into very hot water until it is of the pliability of leather. Cut along the mark with scissors, or tinsmiths snips, according to the thickness of the material. As it becomes cooler it will be more difficult to cut. If any further cutting is to be done, place the sheet-rubber in hot water again and continue as I have described. Next place a sheet of glass on a newspaper on your work-table. Dip the rubber in hot water again, place it on the glass, put another sheet of glass on top of the rubber and weight it down. When cold, the piece will be found to be straight, the cutting having thrown it out of shape.

To bend the hard sheet-rubber into cylinders for tuning coils and other parts, make a wooden mandrel of the desired diameter, measure its surface with a tape measure, and cut the material the desired length. Heat the rubber in hot water. Place two wooden blocks on a smooth surface sufficiently far apart to be even with the edges of the rubber to be bent. Put the hot sheet in position on the blocks and press down the mandrel on its center, gradually curling it into cylindrical shape to fit the mandrel. With thick plates, reheating them several times may be necessary to produce the desired shape. When cold, fill the crack between the two edges with automobile-tire cement. There is a rubber putty-composition for mending tire cuts which is excellent for joining edges. It is best to tie the cylinder tight, with string, until either the cement, or putty, has set.

Polishing hard rubber is a poser for electrical experimenters, as they do not understand how to make the edges of the sheets as smooth as their sides. Therefore, they generally smooth the edges with a file and let it go at that. This mars the appearance of the instruments. By the following process an even polish will result: Fasten a piece of fine-grained sandpaper to the top of your work-table and run the piece of rubber across the sandpaper in a series of smooth strokes, taking care to keep the grain straight. Continue this operation on a second sheet of the finest sandpaper that can be obtained. Wipe off all dust and give the edge a coat of shellac in order to fill the pores. When dry, rub with a piece of felt tacked to a wooden block—the felt to be dampened with oil and FF grade of powdered pumice-stone as an abrasive.

WFAA—"Dallas News," Dallas, Texas.

KVQ—"The Bee," Sacramento, California.

There are students of the problem who believe that press broadcasting stations should handle all news, since the news is really owned by members of the press and is received, first, by them; besides which, the publishers know how to handle the news better than any other agency. Newspapers, usually in the lead of progressive developments, are apt to find it necessary to follow the lead of the aerial pioneers and, in future, carry radio-news bulletins for their clients. Radio is a household contact with the world.

Of the newspaper broadcasters, nine have secured the Class B license permitting them to broadcast on 400-meter wave; they follow: Atlanta "Journal," Atlanta "Constitution," Dallas "News," Detroit "News," Detroit "Free Press," St. Louis "Post-Dispatch," Kansas City "Star," Fort Worth "Star-Telegram," and Los Angeles "Times-Mirror."

The Seattle "Post Intelligencer" now uses the broadcasting station KFC; the Philadelphia "Record" broadcasts through WCAU; "The Ensenada News," Yauco, Porto Rico, uses WGAD; the Indianapolis "Star's" news is released through WOH; the Tacoma "Times" co-operates with KMO; the "Oklahoman" "speaks" its news over station WKY; the Boston "American" uses WGI, and the Memphis "News-Scimitar" announces over WPO. In Canada, two news broadcasters are the Toronto "Daily Star," operating CFCA, and the Winnipeg "Tribune," CJNC.

Among other daily papers said to be planning to use news broadcasting are "The Courier," Grant's Pass, Oregon; "The Gazette," Billings, Montana; "Raleigh Register," Beckley, West Virginia; "Daily Telegram," Adrian, Michigan; "News Herald," Litchfield, Illinois, and the "Pilot," San Pedro, California.

The Radio Primer

For Thousands of Beginners Who
Are Coming into Radio Circles

Weekly A B C of Radio Facts and Principles Fully and Tersely Explained

By Lynn Brooks

HOW are electrons moved about? The chemical action of electrons we have described, although it is not called by that name. You light a cigarette—chemical action changes the tobacco into smoke. An apple decays—chemical action has caused this change. Light a fire—chemical action creates the heat. So it has been found that, under certain conditions, chemical action will feed electrons on one hand and destroy them on the other.

* * *

How can chemical action be started?

Fill a glass jar with an acid. Put into this acid a piece of copper and a piece of zinc, allowing both copper and zinc to stick out of the acid. We have made then what is called a voltaic cell. Usually we just call it a cell. A group of cells together is called a battery. The accompanying sketch shows what we have done. Chemical action will remove electrons from the copper and give electrons to the zinc, so that B has more than the usual number of electrons and A has less than its usual number. B is called the negative terminal; A the positive terminal. Connect A and B by a wire and the electrons will flow through a wire from B to A. They will flow continuously because the chemical action keeps the zinc supplied with them. Connect the two terminals by a wire and show the direction in which the electrons flow and the direction of the current.

* * *

Now that we have electrons flowing, what have we accomplished?

We have produced all the conditions necessary for an electric current. An electric current will result if we keep a voltage between two terminals, as with the voltaic cell, and connect these terminals by a conductor. To study electricity further, we must study the electric current.

* * *

What makes a current?

A flow of electrons makes a current. If we measure the number of electrons flowing, we must state a definite time in which to count them. The definite time is a second. Then, also, we must confine our

Figure 1—Showing the battery where chemical action takes place to produce electricity.

Figure 2—Showing how the electrons travel from the negative to the positive terminals.

measurement to one place in the path of electrons so that we measure current by counting the number of electrons which pass a given point in a second of time.

* * *

What is unity of measurement?

The unit of measurement of electric current is the ampere, just as the measurement of weight is the pound. We say that an object weighs 13 pounds. In the same ratio, we say that a wire carries a current of 15 amperes. Thus you see an ampere means a definite number of electrons passing a point in a second of time. There is an instrument known as an ammeter. It is used to measure the number of amperes. In electricity you will find the word "meter" affixed to various words.

* * *

How can we secure as many amperes as we want? In other words, how can we control the number of electrons passing a given point in a second?

In Figure 2, electrons are shown trying to journey from the negative to the positive terminal. They act like a crowd of people trying to rush out of a building the entrance to which is blocked.

Radio Facts

By Charles H. Plath

ONE thing we must guard against in radio-receiving sets is dust and dampness. The set should be kept, preferably, in a dry room, otherwise moisture will gather in the interior of the works and, probably, form contacts which may lead to the short circuit of the set or give leakage of current. The B batteries should be kept in a dry place, preferably a box, otherwise they will get weak and become "dead." A handy thing around a station is a small long-handled brush. This is used to keep the dust away from switches and parts. Care should be taken to keep the switches and condenser terminals clean, also any other place where dust may collect. It would be a good scheme to clean and dust the set once an evening. This would prevent the dust from collecting in quantity, thereby preventing any leakage to the set. Care and attention should be given to the set as it is delicate. If this is accomplished the set will function.

* * *

AN TENNA insulators should be kept in good condition and wiped off occasionally; because they collect a certain amount of dirt and carbon, especially when near any smokestacks. A film of carbon or dirt over the surface of the antenna insulator will cause leakage and an improperly poor-range set will be the answer. Sometimes other developments happen in the aerial, so it is best to be certain that the aerial is well insulated from the lead-in to the set. The lead-in may be touching some metal near the house, or in the room where it connects with the instruments.

* * *

WHEN a dry cell is run down a very good way to get some extra life out of the battery is to work as follows: Remove the wrapper from the cell and place it in a can 5 or 6 inches high and about an inch wider in diameter than the cell. Fill the can with vinegar and a little salt. The salt should be shaken into the can and stirred well. Let this mixture stand overnight. Next morning, on inspecting the old battery, you will find that it has as much pep as if it were a new one. The battery should be left in this solution until it becomes exhausted. It has given many hours of life beyond the period when it was thought "dead" by the amateur. This is quite an experiment, and every radioman who uses dry cells should give it a trial and watch the results. The scheme comes in handy when in a pinch for some voltage.

Receiving and Denoting Direction of Radio Signals with a Coil of Wire

By *S. R. Winters*

A fine photograph of a "loop," or "coil," antenna, or vertical conductor of electricity. The antenna is shown in place with a complete receiving-set. When supported by a six-stage amplifier, signals are received from France and Germany.

WHEN one or more turns of wire form a square, or rectangular frame it constitutes a coil. A rope, not in use, when forming a series of rings, or a snake gathering itself preparatory to springing toward an object, are common illustrations of a coil. Speaking in electrical terms, however, copper wire wound around a wooden frame—the strands of which wire are spaced one-half of an inch, or one inch, apart—constitutes an antenna for the reception of wireless communications. The "coil," or "loop," antenna and the "overhead," or vertical conductor of electricity are well-nigh household terms emblazoned on the crest of popularity of radiotelephone broadcasting.

Experiments That Lead to Success

A coil of wire as an electrical inductance, other than being the most compact form of antenna, is as versatile as the proverbial Jack-of-all-trades. It may be enclosed completely in a suit-case—or, when rigged-up in a wilderness for the reception of wireless signals, it may determine the direction of the transmitting station from which the communications are coming in. The photograph illustrates a portable radio-direction finder employed by the United States. The coil of wire, forming an antenna, is mounted on a vertical axis on which the frame supporting the strands of wire may revolve freely. Meanwhile, as the coil is rotated about its axis,

a curve is plotted indicating the variations in the strength of the electric current received for the electromagnetic wave approaching from a particular direction. The coil of wire, when employed in this capacity, may be dubbed correctly a direction finder or radio compass.

The electron-tube amplifier, with its score of other triumphs, has been a boon in the use of coils of wire as antennae. In the absence of substantial amplification of the feeble electric-current received in the coil antenna, the few turns of wire on a square wooden frame would be as powerless to produce audible signals as a pyramid. The Radiocommunication Section of the Bureau of Standards, United States Department of Commerce, has conducted extensive experiments with strands of wire wound about a frame as an antenna, and recommends the use of six stages of amplification for satisfactory results. However, with two stages of audio-frequency amplification, wireless signals may be received from nearby stations.

Versatility of the Coil Antenna

If supported by six stages of amplifications, a coil antenna located in Washington, D. C., may record wireless signals from the high-power radiotelegraph stations in France and Germany: An exceptional instance of the capacity of a coil antenna is noted where all the big European stations were received in France by use of a frame containing 200 turns of wire, only eighteen centimeters square. The radiotelegraph signals emanating from the high-power station of the United States Navy Department at Annapolis or Greenbury Point, Maryland, have been recorded in Paris, France, by the use of a coil only ten inches in diameter. The versatility of the coil antenna is suggested by the development of a complete radiotelephone receiving set in an ordinary suit-case with the form of antenna snugly encased in the covers of the traveling bag. It was developed by the Bureau of Standards, the coil antenna and half a dozen audion bulbs encased in a container only 7 by 11 by 18 inches in dimensions.

The coil antenna, other than serving as a direction-finder afield, lends itself to use in locating the direction of wireless signals when installed on seafaring vessels. A system of radio direction-finding for navigation purposes in fog and thick weather has been developed by F. A. Kolster, formerly in the service of the federal government, and F. W. Dunmore, of the Bureau of Standards. The striking directional characteristics of the coil antenna suggest its fitting application on radio-equipped airplanes, especially when flying is to be done in foggy weather or at night. Such a form of antenna is of a discriminating caliber. Its directional tendencies are such that strong signals may be recorded from a particular point of the compass and feeble wireless signals from other directions. Thus, by capitalizing the directional qualities of the coil antenna, interference from transmitting stations whose offerings are not desired, may be curtailed.

Radio amateurs have reported their experiences receiving signals by use of a sensitive receiving-set even when their antennae were altogether discontinued. This phenomenon is explained by the fact that the wiring of the radiotelephone receiving outfit assumed the form of a coil antenna.

New Chief of Radio Corporation Chosen from United States Army

(Courtesy of Radio Corporation of America)

· Major-General John C. Harbord, U. S. A.

MAJOR-GENERAL JOHN C. HARBORD, one of the distinguished officers of the United States Army, ranking only below General Pershing, as Deputy Chief of Staff, will retire, on December 29, to become president of the Radio Corporation of America. The Secretary of War approved his application for retirement. Both Mr. Weeks and General Pershing stated publicly that General Harbord had served in the Army in a highly distinguished and loyal manner, and that his unusual experience as an organizer and executive would insure his success in the business world. The post for which General Harbord has been chosen is regarded of vital importance to the Government as well as the public, since the Radio Corporation of America was formed at the suggestion of representatives of the United States Navy in order that powerful world-wide radio communication, free from foreign domination, might be built up.

Radiograms

The Latest Christmas Radio News Briefly Told for the Growing Army of Radio Fans

THE plan, recently adopted by the police of the country of broadcasting fingerprints of captured criminals to ascertain if they are wanted elsewhere, resulted in the return to New York from Los Angeles of Harold J. Burns, of New York City. Burns, who is said to have used the alias "Darcey," is wanted here in connection with an alleged homicide and two burglaries. He jumped a bail bond of \$12,500 to avoid standing trial on the former charge. The broadcasting of his fingerprints and his apprehension chalk up a new record for radio as a crime deterrent.

* * *

An epidemic of influenza occurred among the officers and crew of the American steamer, "President Roosevelt." The chief officer of the vessel and the purser were among those ill. Supplies of brandy were ordered by radio for the invalids. These were sent on board on the arrival of the steamer at Plymouth and quickly administered. The Volstead act may mean one thing, but radio is ever ready in time of need not only to uphold American liberty, but to protect the sick and forestall epidemics.

* * *

Reports from Croydon, Surrey, England, that a radio engineer had heard parts of the musical concert broadcast from WJZ, of the Westinghouse Electric Company, proved the success of an experiment they were making in increased power. J. H.

Ridley, of Croydon, said he heard the WJZ call and then the strains of a familiar overture. He stated the time was 1.15 o'clock Monday morning, November 27 (8.15 o'clock Sunday night, New York time). Westinghouse radio engineers said they had doubled the power of the broadcasting plant two weeks ago and that on Sunday night atmospheric conditions were at best.

* * *

A system of pilotless airplane control in France has passed a two-day test satisfactorily, according to experts who supervised the trials with a 300 horse-power passenger carrying government biplane that flew over Etampes aviation field. The plane, going aloft with no one aboard, responded to control by radio from the ground, performed all the customary evolutions, and then landed safely. During the tests the machine was frequently lost from sight in haze and clouds, but it was always under radio control.

* * *

Construction of a huge radio transmitting and receiving station in Miami, Florida, for handling South American, Central American and West Indian business to be relayed direct to New York, will be undertaken by the Tropical Radio Telegraph Company, of Boston, a subsidiary of the United Fruit Company, it was announced by George S. Davis, general manager of the radio company. The towers of the sending station will be 437 feet high, higher than any in America, except those at the Arlington Naval Station.

* * *

For the First Time Santa Claus is Delayed

The Capitol Theatre, New York, musical program, broadcast direct from the theatre, proved another big radio success. This radio-engineering feat, by the American Telephone & Telegraph Company, was accomplished by means of a highly sensitized microphone suspended twenty feet from the roof and thirty feet from the stage. The sounds of the music were caught by the amplifiers and then carried over specially equalized telephone wires to station WEAJ and broadcast from there. This is the first time in radio and musical history that symphonic music by a large orchestra was broadcast direct from the theatre during a performance. It is estimated that over 600,000 radio sets caught the concert, reaching a probable audience of over a million persons. Telegrams and letters from stations reporting the success of the concert were received from points in Ohio, Michigan, Minnesota, Nebraska, Ontario, Toronto, the New England States, Kentucky, Virginia, Georgia, and one thousand miles out at sea.

* * *

The great improvement in the power, clarity, and brilliancy of WJZ, Newark, New Jersey, has startled many who have been accustomed to receive this station at the full power of their sets. Listeners in have been compelled to reduce their amplification materially to prevent the signals from being intolerably loud. The explanation of this improvement is that WJZ has a new transmitter. Though the old one was generally regarded as one of the finest in the country, recent developments by the Westinghouse engineers rendered it obsolete, and that it was removed and a new one, up to date in every respect, installed in its place. This new transmitter is rated at double the power of its predecessor. It has 1,000 watts and is greatly superior in the details of its transmitting, modulating, and generating system. It is about three times more effective than the old transmitter. While listeners with electron-tube receivers all over the country have been quick to notice the change, it has been especially pleasing to local owners of either crystal detectors or loud speakers, who are now able to get highly satisfactory results from their instruments.

* * *

Millions have enjoyed the Chicago operas, broadcast by radio. A large audience in and around New York listened to the music of "Aida," played in Chicago and broadcast on the 400-meter wave length of station KYW. The voice of Rosa Raisa was heard as clearly in New York as in the Middle West. Since the opening of Chicago's opera season the radio audiences have heard "Carmen," with Mary Garden singing the leading role, "La Boheme" and "Parsifal." Two operas will be broadcast each week from 8 p. m. to 11 p. m., central standard time.

Santa Claus:—How do they expect me to make my rounds with this radio music to detain me.

Be a National Radio Week Booster

Radio and the Woman

Crystal D. Tector Sends a Goodly Radio Measure of Christmas Cheer and Some Pertinent Advice

DURING the past few weeks, I have received an unusual number of technical questions to answer—and, singular as it may seem, all but a very few sent to me by men. If I should attempt to answer so many questions in my department, I wouldn't have space for half the necessary replies; so I have turned over all these communications to the technical editor of RADIO WORLD and he will answer them in the regular department, "Answers to Readers," from week to week. I deeply appreciate the confidence that so many men place in my ability to help them; but, and I am sure they will agree with me, I have so much else to write about that devoting my allotted space to answers of a technical nature would deprive me of my customary weekly chatter.

THIS is the Christmas Number of RADIO WORLD—a number that goes forth to all of you with a hearty message of gladness and cheer. In a way, it is the forerunner of the National Radio Week Number which will be published the week before Christmas—dated December 23, to be exact—as on that evening the festivities that will mark the celebration of the first big week set aside for radio and the first Radio Christmas, will begin. I believe that every radioist at heart will do something during this week to increase the interest in radio—to bring at least one new fan into the fold. While the great army of radioists is growing faster than the most sanguine of us anticipated, there are millions who, as yet, are uninitiated. And the larger the radio family, the more healthy it will be. The more people enrolled as radio enthusiasts, the faster will perfection in radio development be attained. We pioneers are looking to a day when radio will be declared the most vital, necessary, and important family element in this country.

I SUPPOSE that I have written over a hundred letters to as many women, in the past week, giving all sorts of information regarding the formation of committees, menus for suppers, suggestions for window decorating, banners, signs and what not. I hustled these answers by post because by the time the replies would reach you through this page, the information would be too late for practical use. From the letters received, I feel that the spirit of radio week has become deep-rooted in the heart of the feminine radioist. I felt all along that we women would do our part. And, why not? Radio will interest women just as keenly as it will interest men. I was not at all surprised at the many letters that I have received from mothers whose sons are begging them for sets for Christmas.

THESSE mothers have besieged me with all sorts of queries as to what is the best set to buy, what is needed to comprise a set, how will they know that the apparatus will work after it has been purchased—and all that sort of thing. Now, you cannot blame a mother when her young hopeful demands such an outlay for Christmas. She wants to know that her money will not be wasted; she wants to be sure that she is going to be advised correctly. It has been the greatest pleasure to me to devote my time to these mothers—and it will be a greater pleasure if they will write me when their boys' sets are in operation. If any mistakes occur, I will feel duty bound to help set them right.

"WHEN my little boy came to me the other day," writes one dear mother in Texas, "and told me, so plaintively, that this is to be 'a radio Christmas,' and he didn't want to be

behind the times, I simply couldn't refuse him. We live far from a town of any size—and I must ask you to help me. Tell me what to do and what to buy." Only a stony-hearted woman could refuse an appeal like that—and I am not, My heart goes out to the little ones—especially at Christmas.

DO you know that one of the most wonderful bits of broadcasting was the services of the St. Thomas Church, Fifth avenue, several Sundays ago, and so well described by Peter Gray in RADIO WORLD. I had invited a score of neighbors to my house to hear it. The solemnity of it all, the sacred music, the sermon by Dr. Stires, possessed all the wonderful potentiality and had more effect, if I do say it, than if we had been seated in the great edifice. There was Friend Husband, who hasn't seen the inside of a church since—oh, I'm ashamed to tell—and others equally as guilty, listening in with all the eagerness and interest of the most devoted parishioners. One man who hadn't heard a sermon preached since he was a little boy, remarked that Dr. Stires's words filled him with real inspiration. Others were equally as impressed. It was a soul-satisfying, impressive service. And, let me add, radio is going to bring about the long-looked for return to religious devotion. I don't say it may, I repeat that it will.

FOR many years, and the ministers have admitted it from time to time, the great majority of us have not taken kindly to religion and we have not attended divine worship as did our forebears. Radio will bring religion to the masses as no other element can or will. Some have scoffed that it is not a thing to be broadcast, that nobody wants to hear a sermon. Well, I can truthfully state here that my friends who have asked when they may hear another St. Thomas service will more than fill my radio-reception room. Dr. Stires has done a big thing. He and other ministers who have made the microphone as important as any other phase of divine worship deserve our thanks.

PERHAPS The Saviour himself might have foreseen—in his great human vision—just this present-day occurrence when he said that he could destroy the temple and rebuild it in three days. Perhaps He meant that one did not have to go to church to hear the word of God. Perhaps He foresaw that this mighty and mysterious power of the air would carry His thoughts and teachings to all parts of the earth even unto the remotest hamlet and the humblest home. Don't miss hearing such a service as I have described oh, ye of little faith, for some mysterious element that surrounds it all will awaken in you the belief that a Greater Power is giving unto all mankind the things that mankind is inclined to receive with clouded vision.

AND so it is fitting at this time of the year that we realize at least one great good to the credit of radio. This is the first Radio Christmas. Radio will spread the gospel of Peace and Good Will this Christmas as it has never been spread before—and, in years to come, we will look for our Christmas service by radio just as we will look for every other glad feature of this happy time.

So, here's to a Happy, Joyous, Radio Christmas for 1922.

May we have a bigger one in 1923!

—CRYSTAL D. TECTOR.

Radio Don'ts

DON'T place your battery on charge without making the correct polarity connections.

Don't charge your battery without knowing the density of the acid.

Don't allow the storage battery to get low, due to neglect of attention.

Don't let the water get low in your battery. Always add distilled water from time to time.

Don't fill your batteries on carpet. The acid will eat holes in it.

Don't try to hear signals when the polarities of the B battery are wrong.

Don't light your tubes up to brilliancy. It is not necessary.

Don't try to look for all-wave radio-frequency transformers. There are none.

Don't try to use WD-11 vacuum tubes for radio-frequency work.

Don't try to use WD-11 tubes for super-regeneration. They will not hold out.

Don't try to tune a set by guessing at it. Have someone teach you. You will see a vast difference.

Don't load up the primary of your vario-coupler without loading the secondary.

Don't expect to know how to tune a regenerative receiver the first time you get one.

Don't forget that with a two-variometer type receiver the wave length cannot be had over 500 meters. 2500 meters is not obtainable.

Don't try to hear long-distance stations with a crystal detector.

Don't try to employ 1½-volt tubes in a radio-frequency or superregenerative set. They cannot be used.

Radio's First Big O'er with Gla

(C. Kadel & Herbert)

(C. Kadel & Herbert)

(Above) One important element of a vacuum tube receiving set is the storage battery. The only test one can give this battery to insure life is the hydrometer test. This instrument may be purchased for a reasonable sum. It comprises a rubber bulb at one end. The end of the tube is placed in the liquid and inside the battery containing the acid.

(Left) This is KHJ, "The Times," Los Angeles, California, in operation. Input panel, transmitter panel, power panel, and reading room from left to right. KHJ, on 500 watts, has done a great deal for radio in the Southwest since November 1. One can almost see the millimeter readings. The antenna ammeter reads "8 5/10 amps." "Uncle John," the bedtime story-telling genius, and "Cousin Bill," the humorous-news reader, are "on the job" in the studio, a handsomely furnished room with correct broadcast acoustics. The photograph shows only the instrument room.

(C. Kadel & Herbert)

(Left) That radio broadcasting is useful as well as entertaining is proved by Miss Emily Exner, who keeps a typewritten record of all lectures on cooking and other branches of housekeeping that come to her by radio. She is an ardent radio fan and spent so much time experimenting with her radio set that her mother admonished her and told her it would be more to her credit if she would "learn something about cooking instead of fooling around that old radio machine." Then Miss Exner, unknown to her mother, started to keep a record of the domestic science lectures and, after a time, presented this valuable radiold information to her mother. Now her mother thinks radio "just wonderful."

(Right) William M. Priess, of Belmont, Massachusetts, for many years a resident of New York City, former Army officer, inventor of front-line radio communication sets and other apparatus used by both the Army and Navy during the World War, is fighting in the courts of Massachusetts to retain control of his inventions, for which patents are pending. The battle promises to become one of the bitterest ever fought over radio patents. The courts have just issued an injunction restraining others from revealing the secret operating and processes of manufacture, from experimenting or otherwise interfering with certain inventions which Mr. Priess claims. All the radio manufacturing corporations in the United States are marking time pending the decision of this important suit.

(C. Keystone V)

Christmas Brims Some News

(Left) The storage battery used with vacuum-tube receivers, today, becomes a problem to many radio fans who break into the game with such apparatus. Due to their size, weight, and the care required, some means must be adopted to keep them near the set yet where they may easily be reached. The accompanying photograph shows a suitable shelf which makes a convenient place on which to keep A and B batteries. By following this plan, the batteries are out of sight and the spilling of acid and water on the carpet is avoided.

(Courtesy, Radio Corporation of America)

Separation in Signaling

No. 1,433,500. Patented October 31, 1922. Patentee: Ralph Brown, East Orange, N. J.

SIGNALING circuits in radio are the basis of this invention, letters of patent on which have been granted to Ralph Brown. Where it is desired to simultaneously send and receive in a radio system, as is necessary in the case of radiotelephony, it has been customary to separate the oppositely directed transmission by employing some or all of the following principles: (a) separation by selectivity—that is, the

Latest Radio Patents

Roy A. Weagant's New Device to Prevent Static

No. 1,426,133. Patented August 15, 1922. Patentee: Roy A. Weagant, New York, N. Y.

ROY A. WEAGANT, one of the leading radioists of the United States, has been granted letters of patent on a device to prevent static in radiosignaling. Its purposes are best described in Mr. Weagant's own words, taken from the Patent Office specification.

"I have found by experiment that atmospheric disturbances act as if propagated in a vertical direction only, whereas commercial radio signal waves travel horizontally, or have a large horizontal component of motion. Consequently static disturbances act simultaneously on the parts of a collector system which may be at the same height, while commercial radio waves act simultaneously on those portions of a collector or antenna system which lie in a plane at right angles to the line of travel of the waves.

"I have shown means whereby the effects of the atmospheric disturbances upon two parts of a collector or antenna system may be caused to neutralize each other, while the effects of the signal waves act cumulatively on the receiving instrument, owing

Figure 1—Diagrammatic view of a receiving station showing one form of apparatus embodying Mr. Weagant's invention. A divided collector of the general type is shown associated with receiving and detecting apparatus.

largely to the fact that the antenna or collector system comprises portions which are spaced apart along the line joining the receiving instruments with the source of the signal waves.

"My present invention is an improvement providing a more simple arrangement in which the ends of a plurality of parts of an antenna or collector system are conductively connected in such manner as to greatly reduce the effect of the atmospheric disturbances on the receiving instruments."

For Rheostats

No. 1,433,948. Patented October 31, 1922. Patentee: Joseph Granz, Duluth, Minn.

THIS invention relates more particularly to that type of rheostat used in connection with the smaller forms of electric motors and similar devices. It provides a structural formation and association of the rheostat parts whereby the resistance wire, or filament, having an extended or lengthy nature is effectively supported in a small

The inner and main supporting member or core of the resistance member which is of an open skeleton construction and consists of a pair of flat plate metal sections of split-ring shape secured in properly separated relation by a series of connecting posts with the inner plate metal section attached to the insulating bar or strip 4 to afford the sole supporting means for the resistance member and associated parts.

and compact compass with a very efficient exposure to permit the escape of heat from such resistance wire during actual use; also a simple and efficient construction and arrangement of parts whereby the frictional stress of the adjustable contact shoe upon the resistance winding during an adjusting operation can be materially relieved while electric contact is still maintained.

Novel Battery Container

No. 1,425,721. Patented August 15, 1922. Patentee: Roy William Taylor, Chicago.

MR. TAYLOR'S invention relates to improvements in battery containers. It provides a battery container adapted to house a plurality of dry cells and having means for connecting up such cells in either series or multiple in such a manner that

Figure 1—End view. Figure 2—Section along the line 2-2 of Figure 1.

any cell therein may be replaced at will. It provides, also, a device that can be used with a battery composed of ordinary flashlight cells, suitable for use in wireless telegraph outfits and in apparatus used in electrotherapeutics. It is light in weight, compact, and adapted to be carried about, as in a small handbag. It is simple in construction and operation.

The commutating or switching operation may take place at three different points, (a) in the audio-frequency part of the system before modulation in the transmitting channel and after demodulation in the receiving channel; (b) in the radio-frequency part of the system, and (c) in the circuits leading to the carrier frequency source.

employment of different carriers for transmitting and receiving; (b) separation by balance—that is, the transmitting circuit is rendered at least partially conjugate with respect to the receiving circuit; (c) by geographically separating the transmitting and receiving antenna of a particular station, so that the sending energy from the transmitting antenna will produce a minimum effect upon the receiving antenna.

For the most efficient operation all three of these principles should be employed simultaneously. This is usually possible in the case of a shore station. In the case of a ship set, however, geographical separation of the sending and receiving antenna is impossible, and it has been customary, therefore, to rely entirely upon separation by selectivity and balance.

Mr. Brown proposes to introduce another method of separation in which differentiation between the sending and receiving channels will be obtained upon a time basis by associating the sending and receiving radio channels alternately with the local low frequency line or other type of signaling circuit. Preferably, this switching may take place at a frequency higher than the signaling frequencies and lower than the radio frequencies involved. As a means for controlling the commutating or switching operation advantage is taken of the switching function of a vacuum tube.

At Work on the New Broadcasting Station in Heart of New York City

(C. Underwood & Underwood, N. Y.)

Framework of the radio room of the new broadcasting station now under construction on the roof of Aeolian Building, 42nd street between Fifth and Sixth avenues, New York City. It is expected that this important broadcaster will be completed in about a month. It will be one of the finest and most up-to-date stations in the world.

How the Wind Blows Shown by Radio

A NEW aid to aviators is offered by the Bureau of Aeronautics of the Navy Department by the installation on the 700-foot radio tower at Arlington, across the Potomac River from the Arlington Cemetery, Washington, D. C., of wind-recording devices.

A mast has been erected on the tallest of the three towers, on which is a six-foot wind vane, which, by electrical connections records in the office every vagary of the wind currents at that altitude. The records, it is said, will be of exceptional value to airmen in showing the more constant currents of the upper air. The recording device not only shows the direction of the wind and keeps continuous record of its velocity at all hours, but indicates the velocity on pressing a button. By counting the number of buzzes per minute the velocity can be read at any time.

The continuous record of wind velocities at 700 feet above the ground will be of material aid to aerial navigation over this territory, especially when rigid and non-rigid airships are in flight. Formerly, in order to get the wind velocity and direction, small rubber balloons, hydrogen filled, were liberated, and bearings taken on them at intervals of one minute with a theolite. The angles, when plotted, showed the speed and directions of the winds that drifted the balloons at each altitude. The height of the balloons at the termination of each minute of flight was predetermined by the weight of

the rubber and the amount of ballast lifted. The balloons were usually inflated so that they would rise at the rate of 200 metres per minute. When the sky was clear and cloudless they were often followed, through the instrument, to heights of 10,000 feet or more.

There are often times when the fog, low clouds, rain or snow interferes with the observation of the balloons, so that the advantage of having wind instruments on high towers is apparent. While the pilot balloon method is still widely used elsewhere, in the near vicinity of Washington prospective fliers need only telephone to the recording office to receive the readings at any moment.

The triple register, as it is called, also makes a continuous record of sunshine. The transmitter, placed near the wind mast, indicates on the register every minute of bright sunshine that strikes the tower. The purpose of the instrument is to show whether there is sunshine or cloud above any low hanging clouds or fogs that may prevail near the ground.

Continuous records at 700 feet above the ground level will be compared with those taken at various stations at the ground level, one of which is at the foot of Arlington tower, and will be useful in determining the increase of wind with altitude. The data will also be of value to engineers, the department says, in using the readings for the determination of wind pressures on structures.

Why Magnavox is the Reproducer Supreme

OFFICIAL tests with the oscillograph prove that the Magnavox electro-dynamic receiver reproduces incoming wave forms with maximum accuracy.

The Magnavox can be used with any receiving set—the better the set, the more Magnavox can do for you.

When you purchase a Magnavox you possess an instrument of the very highest quality and efficiency.

R2 Magnavox Radio
with 18-inch horn

(as illustrated)

This instrument is intended for those who wish the utmost in amplifying power; for clubs, hotels, dance halls, large audiences, etc. It requires only .6 of an ampere for the field.

Price \$85.00

R3 Magnavox Radio
with 14-inch horn

The ideal instrument for use in homes, offices, amateur stations, etc. Same in principle and construction as Type R2.

Price \$45.00

Model C Magnavox
Power Amplifier

For use with the Magnavox Radio and insures getting the largest possible power input.

2-stage \$ 80.00
3-stage 110.00

Magnavox products can be had of good dealers everywhere.

Why I'm Proud of My Home-Made Set

By A. J. Weis

373 East 204th Street, New York, N. Y.

"Close-up" of Mr. A. J. Weis and his home-made receiving set.

IN response to the request in RADIO WORLD for pictured information, I am enclosing a photograph of the receiver which I built and with which I am getting what I consider remarkable results. I regret that I have nothing to offer in the way of new wrinkles or phenomenal hook-ups, but I feel that I have succeeded in finding a better way of doing one thing at least, and that is obtaining a well-balanced panel lay-out. This, I find, has been sadly overlooked in most home-made sets and in many commercial sets as well. I have also, I think, succeeded in arranging the accessories that make up a

receiver, in an orderly and convenient manner. The table on which my set appears, in the picture, is home-made. It contains a compartment in the rear for the B batteries, four in number. The cover of the table is hinged, permitting ready access to the batteries at any time while the set is in operation. On the lower part of the table is a shelf, placed at a convenient height, which holds the A battery. The leads are brought out at the top, through holes drilled in the cover. The battery binding-posts are all in the rear of the cabinet. This gives the panel a neat appearance and keeps the

Over the Top! (Radio Version)

(Cartoon by Lawrence B. Hinckley)

conglomeration of wires away from one's hands when manipulating the dials. The loud-speaker is placed in the rear, on a small shelf. This keeps it out of the way and at the proper height. Notice that the amplifier is built into one cabinet with the receiver proper. This cuts down the length of the cabinet by one half.

The receiver is an ordinary regenerative one, using a coupler with a condenser tuned secondary, and a plate variometer for regeneration. V-T 1 and V-T 2 tubes are used exclusively and respectively for detection and amplification. Other parts of the set are as follows: home-made 180 coupler, Mignon condenser, Atwater Kent variometer, Paragon rheostats, Radio Corporation transformers, General Radio Corporation dials, switch points and levers, also a Radio Corporation potentiometer.

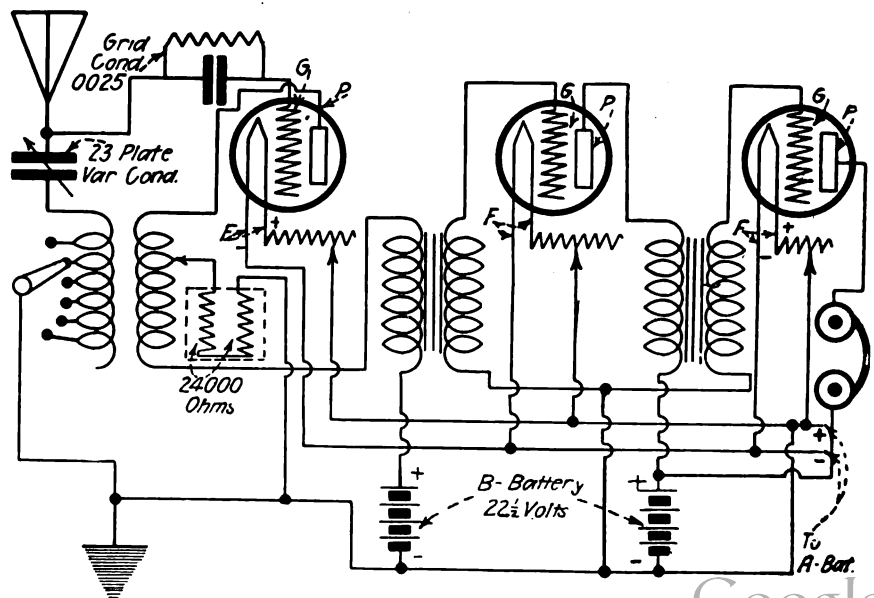

The following is a list of stations I have copied to date: WJZ, WWZ, WHN, WOR, WEA, WAAM, WBS, WLAW, WGY, WHAZ, WBZ, WNAC, NOF, WOO, WHAS, KDKA, WOC, WFI, WMAK, WRW, WNAQ, WSB, WIP, WWJ, KYW, WGM, WHB.

I have letters from most of the above stations, proving that I have actually received their programs.

While this may not seem such a remarkable record to many radio fans who have covered a still greater distance with their outfits, it does mean a great deal to me, since I built the set myself.

Uses Miniature Resistances in Plate of Single-Circuit

EDITOR, RADIO WORLD:—Enclosed is a wiring diagram for a single-circuit receiving set with which I have derived exceptional results. With this circuit and a one-step amplifier, I have heard the following stations: KDKA, WWJ, WSB, PWX, WGY, KFAF, NOF, WHB, WOC, WBAP, and others too numerous to mention. If you will notice the diagram, I am using non-inductive resistances in my plate circuit which seem to hold my tube steady and prevent it from going into oscillations, for which the single circuit set is noted. On several occasions, I have adjusted my set to such a fine degree that I could hear violin music from the lowest to the highest notes without the bulbs going into oscillations. This also makes it very selective. When you adjust your set you do not seem to have other high-power stations breaking through.—Fred Gretsch, 1311 East Condit Street, Decatur, Illinois.

Hook-up of Mr. Gretsch's set as described in his letter to Radio World.

Inductance and Resistance

I DON'T quite know what this title means, but for all of that it seems to me rather good. I came upon it in the radio section of a metropolitan newspaper with which I happen to be familiar, says Robert L. Duffus in "The Globe," New York. It was part of a discussion of Oscillations, The Damping Constant, Filter Tuning, Microhenries, Microfarads, and other subjects connected with the miracle of sending a jazz concert or a bed-time story through the air from Newark to Oyster Bay. The miracle was impressive, but it seemed that no one without a passionate affection for logarithms and diagrams could have made head or tail of the explanations.

I pointed this out to a representative of the circulation department. The man in the street wouldn't read such stuff, I said, and if he did read it he wouldn't understand it. What he wanted was simplicity. He couldn't digest anything complex, or—as Noah Webster would say—esoteric.

The circulation man listened to me patiently. He had but one answer. He didn't know what the man in the street thought about these technical subjects, but he did know that he liked to read about them. There was no doubt about this, for he had figures to prove it.

Who read the radio section? Boys and young men very largely. Most boys liked to tinker with scientific toys and many of them knew a lot more about electricity than college professors had known a few years ago. Logarithms and technical jargon were as easy as baseball to these young people.

But the boys didn't have it all to themselves. Every one who was interested in the wireless telephone learned about it, just as they had previously learned about automobiles. Age wasn't a barrier. Men who would have regarded a technical discussion of the economic cycle or European politics as clear beyond them easily got a grasp on the just as difficult subject of electricity.

The explanation is one long known to educators. We all learn more easily when we are interested than when we are not. A boy may go to school for years and make practically no progress. Then he discovers that he has a personal need for mathematics or science, and he soaks it up almost overnight. It was interest that was lacking, not intelligence.

Probably this is true of multitudes whom it pleases the intellectual snobs to regard as hopelessly stupid. Somehow or other, life has failed to engage their interest except at a few points. There is no reason why the schools, and later the newspapers, magazines, and theatres, should not get them excited about a wide variety of subjects. The trouble is that scientists, artistic persons, and others, who regard themselves as out of the ordinary, usually won't take the trouble to tell the man in the street about the thrilling things they know and feel.

Yet it can be done. If "inductance and reactance" can be made comprehensible to the man in the street so can anything else that it is valuable for him to know.

Another Radio Club

THE Highway Radio Club was organized November 23. Applications for membership may be filed with William C. Burns, corresponding secretary, 2655 Mansfield

Any single copy of Radio World, beginning with No. 1, mailed on receipt of 15 cents postpaid. Any seven issues for \$1.00. The full 20 numbers sent for \$2.90. Or send \$3.00 for 6 months (26 numbers) or \$6.00 for 1 year (52 numbers) and have your subscription start from No. 1. Radio World, 1493 Broadway, New York.

Let Radio World Test Your Goods

MANUFACTURERS, send a sample of your goods to our Technical Editor, Fred Charles Ehlert, 9006 Pleasant Street, Queens, Long Island, New York. It will be carefully tested. If your goods satisfy our experts, RADIO WORLD'S endorsement will be published in our merchandise department without charge or obligation of any kind on your part. When the radio purchaser sees a published test in RADIO WORLD with the seal accompanying this editorial attached, he will know that the product stands for perfection and has the guarantee of RADIO WORLD. RADIO WORLD is rendering a service through its testing department that is prompt, accurate and produces results. All goods will be returned to manufacturers, after testing, provided stamps are sent for that purpose.

Rheostat Has Novel Contact Arm

(Manufactured by Sunraid Radio Co., New York, N. Y.)

To overcome the difficulty between the coils of resistance wire and the contact arm, the Sunraid rheostat uses a contact which is maintained by the constant pressure of a spring on a small

brass plunger. The coils are wound in the ordinary way on a strip of heat-resisting compound and then set into a condensite cup so that it forms a ring approximately two inches in diameter. To fit the control knob shaft, a piece of nicked brass is fitted into a clamp at one end and a tube at the other to hold the compression spring and the plunger contact. Either panel or base mounting may be used in adapting this rheostat in the set. The condensite cup is provided with screw holes so it may be fastened to the panel.

National Radio Week Special Number!

Remember "This Is a Radio Christmas"

and that millions of dollars will be spent during the holiday time for radio gifts.

SECOND NATIONAL RADIO EXPOSITION, direction International Trade Exposition Co., Chicago, January 13 to 20, inclusive, 1923, George A. King, director of publicity, 417 South Dearborn Street, Chicago, Ill.

PERMANENT RADIO FAIR FOR BUYERS, Hotel Imperial, New York City. Open from September, 1922, to May, 1923.

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, December 21 to 31, Colwell & Korbell, Fisk Building, New York City, directors of publicity.

SOUTHEASTERN RADIO EXPOSITION, Auditorium Armory, Atlanta, Georgia, December 4 to 9, inclusive. Co-operative Radio Sales Assn., 205 Peachtree St.

SECOND DISTRICT RADIO CONVENTION, Hotel Pennsylvania, New York City, March 1, 2, and 3, 1923.

At the Permanent Radio Fair

PERMANENT RADIO FAIR, INC., a centralized exhibit of reliable radio merchandise at the Hotel Imperial, Broadway and 32nd Street, New York City, is attracting considerable interest among radio buyers and dealers. Only the products of representative manufacturers are on display. The exhibits, enclosed in handsome show-cases in the attractive Red Room of the Imperial, offer prospective buyers an opportunity to secure a comprehensive survey of the radio field.

The radio fair is doing everything possible to boost radio and to stimulate favorable public opinion toward radio in general and to exclude all whose product is of such character as to bring radio into public disfavor.

Another very interesting feature of the Permanent Radio Fair is the radio phenomenon, "Madame Radora," the life-sized automaton who bows and talks in human fashion.

No Free List

To many anxious inquirers: RADIO WORLD has no free list. One copy is sent as a voucher to each advertiser or advertising agent represented in current issues. All other copies are paid for on subscription or through the news trade.

With the DX Night Owls

Wide Range with One Detector Tube

EDITOR RADIO WORLD:—I have been reading some of the long-distance receiving records published in RADIO WORLD. I would like to submit mine. I do not think they can be heat easily, considering my equipment. I have heard as far east as WBZ, Springfield, Massachusetts; as far south as WIAF, Nola Radio Company, New Orleans, Louisiana; as far west as KHJ, Los Angeles, California, and as far north as CKCK, Regina, CKCK and CJCG, Winnipeg, Canada. I have heard KZN, Salt Lake City, Utah and DD5, DN4, KEAF, and KLZ, Colorado. I have heard broadcasting from twenty-five States and two provinces in Canada. All these stations (75), were heard with only one detector tube, with 22½-volt battery in plate circuit. I use a home-made, three-spider-web regenerative set. On the night of November 21, I heard WLAG, WGY, WSB, KDKA, WJZ, WDAF, WIAO, WEA, WHB, WBZ, WWJ, WCK, WHAS, WOC, WJAP, KSD, KYW, WOS, CJCG, WEAB, DN4, WGM, WBAP, WDAJ, WBL, WFAA, KHJ, WPA, and CKCK using a one-step amplifier with 45 volts on the plate. I use Cunningham tubes and a Thordarson transformer. I don't think this record can be beat with the same equipment.—Arthur Lindstrom, 4th Street, Baraboo, Wisconsin.

* * *

With a Home-Made Crystal Set

EDITOR, RADIO WORLD:—In your issue the record of E. S. Morrison, Ashland, Oregon, with a Westinghouse R-C set, in RADIO WORLD, No. 34, November 18, 1922.

We think we are making records here. With a home-made crystal set we hear WGG, KDKA, WSB, Detroit, Cincinnati, Minneapolis, Fort Worth, Dallas, Denver, etc.

With a home-made one-tube set we pick up Los Angeles, San Diego, San Francisco, Portland, Atlanta, Schenectady, Springfield, Havana, Cuba, and Calgary, Canada. If better records are made, who made them? We will make an affidavit as to ours.—N. R. Brown, Olathe, Kansas.

* * *

A Claim from New Orleans

EDITOR, RADIO WORLD:—I am not trying to claim the record for receiving. I live in New Orleans, Louisiana; but with a single tube and one coil consisting of 60 turns and rotor, I hear regularly Denver, and Colorado Springs, Colorado; Chicago; WWJ, Detroit; KDKA, Pittsburgh; WOC, Davenport, Iowa; Fort Worth and Waco, Texas; Atlanta, Georgia; WSB, WGM, and others. There are three stations in this city. If I do not wish to hear them, I can tune them out. Under favorable conditions I hear Portland, Oregon. How's that?—R Diamond, 413 Royal Street, New Orleans, La.

* * *

On a Crystal Set

EDITOR, RADIO WORLD: I have picked up WOC, WCAL, WWJ, WCX, WHAS, WOI, KSD on my crystal set. I accomplished this all within the past week; for heretofore, believing long-distance reception with crystal sets impossible, I never attempted to "get" any distant stations. On November 19 I attempted to pick up WCAL, Northfield, Minnesota, about fifty miles distant. I not only got

them, but WOC, Davenport, Iowa, as well. Since then not a day has gone by but I have picked up one or two long-distance stations. Although this seems incredible, it is a fact. I have heard these stations very well considering the circumstances. I hope to better this record before long.—Bill Keating, 1516 Second Avenue, South Minneapolis, Minnesota.

* * *

Tuned Out WJZ for WOC

EDITOR, RADIO WORLD: On November 12 at 9:55, eastern time, with WJZ on the air, I tuned him out and received WOC, Davenport, Iowa, on the loud-speaker; just as loud as WJZ or any other local station.—G. F. Olson, 2 Jerome Avenue, Belleville, New Jersey.

RADIO WORLD as a Christmas Gift

Have You a Friend Who Is Interested in Radio as an Amateur or a Fan?

IF so, you must know that such a friend would welcome a yearly subscription for RADIO WORLD from you. Send us \$6.00 and we will place the name of your friend on our mailing list for the coming year, and also we will send a special notification to your friend to the effect that RADIO WORLD will be sent for 52 weeks to his address with your compliments. Send in a yearly order, so that the first copy and our acknowledgment of your courtesy to your friend will be received before Christmas.

Address: Subscription Department, RADIO WORLD, 1493 Broadway, New York, N. Y.

Christmas Gift Subscription Blank

RADIO WORLD,

Answers to Readers

I INTENDED to construct a cabinet 8 x 15 x 30 inches. I will divide this into four compartments so as to hold. 1. a honeycomb coil regenerative receiver; 2. A telephone head set; 3. Battery; 4. My 6-volt A battery. My A battery will be about 12 inches from the receiver. Do you think this will interfere with satisfactory reception?—John Mullenhauer, Poughkeepsie, N. Y.

The length of the A-battery leads make very little difference in the efficiency of a set. The length you mention is all right.

Can I use Westinghouse type WD-11 tubes for amplifiers? If so, what kind of amplifying transformers must I use? Also, what kind of grid condenser and leak will I need for the detector tube?—W. E. Gilbert, Jr., Box 1282, Alliance, Neb.

WD-11 tubes may be used as amplifiers. The regular standard transformers may be used, but the Sleeper transformers work best with this type tube. It is not essential that a grid condenser, or leak be used with this type tube, but we advise you to try it out as an experiment. A .00025 mfd., condenser will answer the purpose and a 1-megohm leak.

I have a two-stage honeycomb outfit with 100 feet of aerial. I was receiving WJZ and WOR wonderfully. I disconnected my tuner and replaced it again exactly the way it was before I removed it. Now my receiving is reduced fifty per cent. in loudness. I have tested my batteries, both A and B, and find them fully charged.—Paul Haffner, Woodcliffe, N. J.

Undoubtedly the trouble is caused by what is known to radiomen as "fading." This is a condition over which we have no control. It sometimes happens during reception, and frequently becomes so loud that the vacuum tubes are paralyzed and reception ceases. Then it is a good plan to disconnect the B battery, let the tubes recover, then replace the B battery with the amount of voltage somewhat reduced during the period of the maximum reception. Try smaller coils on the secondary and the tickler.

I would appreciate a diagram with complete directions regarding the construction of a radio outfit.—Herman Brush, Mt. Carmel, Ill.

RADIO WORLD, No. 33, dated November 11, page 4, will give you a complete diagram and all the necessary data you need.

How can I make a charger for alternating current?—C. E. Chamberlain, Jaffrey, N. H.

Purchase a battery charger from some reputable concern. These chargers are more efficient and compact than most troublesome, noisy, home-made affairs.

I have a regenerative set with one step of radio-frequency amplification. I cannot receive long-distance stuff except the local stations. Will you please publish a good hook-up?—Reader 319, Louisville, Ky.

(Continued on following page)

Quality, Design + Workmanship + Material = **RELIABILITY**

RADIO-A RE-CHARGER

Simple to Use

Just plug in at any 110 v. A. C. lamp socket—attach clips to battery—turn on current and you have your own charging plant.

A compact portable Recharging unit that will fully charge a 100 AH battery overnight for 5c. to 10c.

Answers to Readers
(Continued from preceding page)

In this issue there are two good hook-ups of radio-frequency. We advise you to see RADIO WORLD No. 19, dated August 5, in which appeared article on radio-frequency by George W. May. This should set you right in fixing up your set.

Please publish a hook-up with a variometer in series with the primary of the loose coupler?—Harry Homer, Glen Cove, L. I.

Hook-up requested by Mr. Harry Homer, Glen Cove, Long Island.

The above sketch shows the correct hook-up for such an arrangement. Care should be taken in checking up all connections and battery polarities.

I am planning a 1-tube hookup as illustrated in RADIO WORLD, No. 30, dated October 21, page 7, and would like to add one step of amplification. Please send me a wiring diagram.—Richard Burgess, Burlington, Vt.

There appeared in RADIO WORLD, No. 22, dated August 26 an article by Fred. Chas. Ehlert, "My Detector and One-Step Amplifier." This describes the exact receiver you have in mind. A complete diagram is also published.

I am building a honeycomb coil regenerative set. I am told that if I short circuit the tickler coil I will get efficient spark reception. Would there be any advantage in using loading condensers to load the primary and secondary of my set to larger capacities?—Maxwell Murphy, Eastport, Maine.

Do not short circuit the tickler coil or the signals will be very weak. See RADIO WORLD, No. 24, dated September 9, page 9.

CHAMBER of COMMERCE**

and sanction of the Radio
Apparatus Section of the

**ASSOCIATED
MANUFACTURERS of
ELECTRICAL SUPPLIES**

**Grand Central Palace
New York**

December 21st to 30th

(Sunday excepted but Christmas Day included)

This first really comprehensive Exposition to be staged in a manner worthy of a great industry includes such representative exhibitors as:

- Western Electric Company, Inc.
- Radio Corporation of America
- National Carbon Company
- C. Brandes, Inc.
- Sleeper Radio Company
- General Insulate Company
- Executive Radio Council
- Coto-Coil Company
- Weston Electrical Instrument Co.
- American Radio Relay League
- Stromberg-Carlson Mfg. Co.
- Holzner-Cabot Company
- Clapp-Kastham Company
- Dublier Condenser Company
- DeForest Radio Telephone & Telegraph Co.

All of the above and other leading manufacturers have contracted for space and many more are at present negotiating for representation. The opportunity to display Radio products to thousands of buyers during the holiday season is an unusual one. The exposition will be one of New York's big features in connection with National Radio Week.

A Complete Success

Radio World Reader So Describes His Tests with Mr. C. White's Radio-Frequency Regenerator

EDITOR, RADIO WORLD:—I believe your readers will be interested to know that the radio-frequency regenerator described by your correspondent, Mr. C. White, in RADIO WORLD No. 28, dated October 7, has proved, in my case, a complete success. Using the new circuit I can hear distinctly, practically all the important broadcasting stations east of the Rockies.

I have made just one change in Mr. White's design, and that is the use of a plate variometer instead of a tickler. The value of the circuit seems to be, however, not so much in long-distance reception, as to the remarkable purity of voice and music, due to the use of a crystal detector between the two bulbs.

I am using Myer bulbs as I find that their stability is a great help in securing good results.—G. L. Michaud, 1020 Hill St., Ann Arbor, Mich.

* * *

Trying Mr. Miller's Hook-Up.

EDITOR, RADIO WORLDS—In your issue No. 30, dated October 21, you publish a novel hook-up by Mr. W. Miller who uses a honeycomb coil for tuning. In your issue No. 34, dated November 18, another of your readers claims that he bettered Mr. Miller's circuit by using a variometer. I claim to have had practically the same circuit in use since April 25. It works better the way Mr. Miller has it hooked up, with the exception that the condenser is across the honeycomb D-L 75 instead of D-L 50. I have tried out both against mine; and, I think that, next to mine, Mr. Miller's works the best. I would like to hear from others. Just a "bug."—Ray Chittenden, 37 Petrel Street, Rochester, N. Y.

THE ONLY GENUINE AND GUARANTEED

"All Wave" Coupler

TRADE MARK FLAT AND BANK WOUND

Wave Length, 150 to 3,000 Meters

Eliminates the use of all Variometers, Varicouplers and Loading Coils, inasmuch as it performs in one compact unit the functions of all of these devices combined.

For the Novice—The six efficient hook-ups given free with each "All Wave" Coupler enables the greenest novice to attain the same results attained by the expert in building the simplest, most compact and most efficient radio receiving set possible.

Be Prepared—For the higher wave lengths that have been and will be allotted to broadcasting stations because of their ever-increasing number. BUILD a set that cannot become obsolete.

Unusual Results Attained—Individual users of the "All Wave" Coupler have written us that in Rhode Island it is nothing unusual to bring in stations as far south as Havana, Cuba; while in Mobile, Alabama, Newark, N. J., is brought in daily.

Beware of Imitations—of the "All Wave" Coupler, which is guaranteed with a money back to operate as advertised. Look for the trademark, "All Wave," on the rotor, also the six efficient hook-ups in the box.

The Biggest Show on Earth

RADIO played a great part in the football contests of the gridiron season which closed Saturday. The seating capacity of stadiums no longer limits the number of people who can enjoy the plays, the cheers and songs of the collegians, says "The Times," New York. One of the features of the season was the broadcasting of the Princeton-Chicago game by station WEAJ in New York. A long-distance telephone line connected the microphone at the Chicago gridiron direct with radio apparatus in New York, so that the entire country was in tune with the game at Stagg Field. Radio has made it possible for those listening in to hear the songs and clamor of the crowd even before some of those assembled at the gridiron. Sound travels approximately 1,000 a feet a second. Radio travels 186,000 miles a second.

The music of Harvard's band in the Yale Bowl, Saturday, November 18, surged through the bowl at the slow speed of sound, but the radio microphone picked up the music and sent it through space at the speed of sunlight, 186,000 miles a second. By the time people 1,000 feet away from the band heard the Harvard and Yale music, radio had transformed the same music into ether waves, with velocity sufficient to carry it around the world seven and one-half times, while the sound waves were covering 1,000 feet across the Yale Bowl.

Radio provides the biggest show on earth at the present time. The radio audience numbers millions, and consists of people representing every country in the world. The cast of the radio show is unlimited; all the world is the stage. And as all shows hold feature performances so does radio. World series baseball games, play by play, direct from the diamond; prizefights direct from the ringside, blow by blow, mingled with the sound of the gong and the outcries of the crowd; football games direct from the gridiron, yard by yard, backed by the college songs and cheers; track meets, lap by lap, and now the latest feature added to the program is opera.

Radio Times Changed

LAST year at this time radio sales managers were sitting in their offices with the doors locked to prevent the entrance of dealers who wanted to buy apparatus, says "The Mail," New York. The sales managers were very independent. Sometimes they would do a man a favor by booking an order and sometimes they would not. Sometimes they would grant a man the courtesy of an interview, but more often they were inclined to "turn him down cold."

The writer commented on this last spring. These sales managers were told that they would some day change their opinions.

Things are very much different today. The sales manager's office is wide open, but the average office is empty. Frantic dealers are sane, and they are not in the habit of making pilgrimages to the sales managers' sanctums. Instead the sales manager is making frequent calls on the dealer, and the feet that used to rest on the desk-top are now coming in contact with the hard pavement of the streets.

No Free List

RADIO WORLD has no free list. The only copies sent out by the publishers are to fill the ever-increasing orders of the American News Company, the large numbers of subscription orders received at the office of publication, and one voucher copy to each advertiser and advertising agent represented in current issues.

- WRAA—Rice Institute, Houston, Texas.
- WTAU—Ruegy Battery & Elect. Company, Tecumseh, Nebraska.
- WOAN—James D. Vaughn, Lawrenceburg, Tennessee.
- WOAL—William E. Woods, Webster Grove, Montana.

Radiophone in Each Room

ACCORDING to Michael Emmett, the Palace Hip Theatre, in Seattle, Washington, holds out a novel inducement to the artist in the way of a radiophone in each dressing room. Here the artist can sit while making up, or between shows, says "Vaudeville News," and hear lectures, sermons, music, etc. Its effects are marvellous, for the artist keeps out of the wings, being interested in the radio, and happily forgets that evil tendency of "talking shop." This seems to be a new blessing to the theatrical world. Mr. Joseph Muller, manager, and the stage hands do all in their power to bring happiness to the artists while playing in Seattle, according to Mr. Emmett.

Phono-Phane Permanent Radio Detector

The only fixed radio detector requiring no adjustment. Used in place of crystal or vacuum tube detector. Gives excellent quality of sound without distortion, battery or tube noise. Detects telegraph signals at several thousand miles. Detects broadcast music more clearly than vacuum tube detector, and requires no amplification where the incoming signal has sufficient strength to actuate the sensitive phone. Ideal for use in regenerative circuits. Handsome, substantial, suitable for assembly in the finest radio equipment. Guaranteed against imperfection \$3.50 or faulty operation. List each.. **\$3.50**

Saturn Automatic Plug

The only perfect automatic plug, no need to take apart to make connections. First insert the terminals into the "Saturn" and a perfect connection is made. So constructed that pulling of the cords makes the connection more positive. **\$1.50**
List each

W. J. Burns to Speak on Police Radio

HOW radio is employed, and may be employed, by police and other agencies for the detection of crime will be demonstrated in an intensely interesting manner at the American Radio Exposition, Grand Central Palace, New York City, December 21 to 30, inclusive. William J. Burns, chief of the United States Secret Service, is much interested in radio and is using it in his department. He will speak at the exposition. In accepting the invitation to speak, Mr. Burns said: "It will be interesting to compare the archaic methods of criminal investigation of the past with the methods of the present; also, what we hope to do in the future with radio—which is the last word. I will explain also how we expect to use radio in the next Bureau of Identification which we are at present organizing in my department."

Several demonstrations will be made to show how radio has been employed by police chiefs of European cities.

A concentrated effort is being made by the management and the numerous exhibitors participating in this exposition to make it thoroughly representative of what is best in the radio industry. Many unusual "stunts" and demonstrations are planned.

Additional contracts for space were signed by the following concerns: Jewett Manufacturing Corporation, American Radio & Research Corporation, Electric Storage Battery Co., Ackerman Bros. Co., Inc., Electric Record, Feri Radio Manufacturing Co., General Lead Batteries Co., Copper Clad Steel Co.

Point It East!

A MILLION-WATT vacuum tube has been built in Schenectady which is expected to carry radio-telephone conversation across the Atlantic. We sha'nt mind, as long as they keep it pointed east.—"The Plain-Dealer," Cleveland.

Something Brand New in Antenna Wire

Jobbers and Dealers—Stock this now for Fall Trade

Here is an Antenna Wire that will at once appeal to the radio enthusiast. It has a real selling argument in that it is different and better than any makeshifts to date.

This new wire, hard drawn from the finest copper, has a corrugated surface with 10 collecting points on its circumference. This gives a greater collective surface and the points give a greater gathering surface.

The result is extreme sensitiveness, and an increase in the range and clearness of any set, from the simplest crystal type to the finest V. T. Receiver.

Packed in neat cartons of 100 feet, 200 feet and 500 feet.

Price **\$2.00** per hundred prepaid

Remote Control a Future Use of Radio

As we listen in on our little receiving sets we think that radio is a great thing, and one deserving of much attention. But yet, do we ever consider the many other uses that radio waves may be put to beside that of broadcasting intelligence and music? Remote control of mechanism is also possible with these very same waves, says "The Globe," New York.

With the development of amplifiers there has come the increasing possibility of using radio to control the operation of any machinery or motion at a distance, by use of a relay or switch connected to special radio receiving apparatus. In order to accomplish this, signals are transmitted by radio, and are received by a receiving station employing a very sensitive amplifier and specially designed relay device. This relay is then connected to such mechanism as it is desired to operate at the receiving station. Such mechanism can be an electric light, an electric bell, the control lever of an airplane, the switch of an electric power line, or, in fact, most any mechanical or electrical device. A disadvantage of radio control is that the receiving apparatus must be in continuous operation, with consequent consumption of power from the batteries or generator which supplies current to the receiving set. For certain purposes, however, this is not too great an expense to keep the use of distant control by radio from being feasible. The use of radio in this way is being considered by a number of electric power companies for operating switches at distant power plants or stations.

At one of the recent manoeuvres of our fleet a battleship without a soul aboard, equipped entirely for radio control, was sent out to sea, and acted as an effective moving target for our gunners on other ships.

The Voice Amplifier

As it is becoming popular to broadcast events which take place miles away from the broadcasting station proper, it has become necessary to make use of a "voice amplifier." This device enables the reproduction at the station of sounds picked up a great distance away, without the loss of clearness or intensity at the broadcasting transmitter.

Subscribe for RADIO WORLD. \$6.00 a year, \$3.00 six months, \$1.50 three months.

Attention, Newsdealers

You should keep a good supply of back numbers of RADIO WORLD on hand all the time. It has been the experience of many dealers that a purchaser of RADIO WORLD for the first time will almost immediately want the back numbers, some of which are already out of print and some of which are difficult to get. THE PUBLISHER WILL FURNISH BACK NUMBERS TO DEALERS DIRECT OR THROUGH THE AMERICAN NEWS CO. AND ITS BRANCHES. Dealers should hold their unsold copies for a reasonable length of time. RADIO WORLD of October 28 contained a full page of contents of back numbers to that date. 15 cents per copy; any seven numbers for \$1.00. RADIO WORLD, 143 Broadway, New York.

How Clemenceau's Speeches Were Amplified from a Truck

(C. Kadel & Herber.)

To insure the vast audience that wished to hear Georges Clemenceau, "the Tiger of France," the Western Electric Company used a radio speech-amplifier mounted on an automobile truck stationed outside the hall where the speech was delivered. The photograph at the left shows the amplifying truck; at right, D. C. McGalliard operating the amplifier.

CHARLES R. ABLETT CO.

199 Fulton St., NEW YORK CITY

THIS receiver is equipped with binding posts which are normally short circuited for 300 to 6800 meters by which wave lengths up to 23,000 meters may be received by the attachment of loading coils. Capacities of proper loading coils for above are: Primary 50; Secondary 50; Tickler 30 millihenries. While the receiver is provided with a "standby" or untuned circuit, it also has an unusual degree of selectivity. Although primarily designed for the more advanced fields of Radio work, or the laboratory, the simplicity of arrangement and beauty of finish make it unusually desirable for the radio club or for the individual who desires the finest equipment obtainable for his home or office. In the receiver, Bakelite tubes, threaded, provide the forms on which inductance coils of high frequency cable are bank-wound. After assembling, the coils are impregnated with an insulating compound, in vacuum, and thoroughly baked. The inductance switch controls a mechanism whereby the different sections may be connected, completely disconnected and opened, or completely disconnected and individually short circuited. This arrangement is important for, by it, each coil has a natural period when connected which is less than the shortest wave length in the receiver's range. The reception of parasitic signals is overcome, the absorption of desired signals by the coils is minimized, more energy is forced to the detector and on all wave lengths the interference is reduced.

VOLUME TWO OF

They Not Only Pump Air to Deep-Sea Divers But Keep in Touch with Them by Radio

When a man goes down into the ocean's depths, today, he does not have to worry that the telephone cable will break. He gets his instructions and also talks to the ship above by radio. This photograph shows one of the pumps that supply the diver with fresh air and, alongside of it, the transmitting set that makes it possible to keep in touch with him by radio. The aerial for the diver is an insulated wire strung inside his air-cable. He uses a waterproof set strapped to his back. This set is tuned to the wave length of the ship afloat. While submarine wireless is quite an everyday affair, the communication between the diver and ship is a recent improvement.

TO the uninitiated, it is a constant source of wonder and ever increasing mystery as to how deep-sea divers receive signals while under water. Both the United States government and private individuals have made experiments which prove that radio waves transverse water with the same ease as they transverse the air. It is no mystery, then, to understand that if you use a very well-insulated wire for an aerial communication may be carried on through the medium of water. In a series of tests made by government experts, it was established that a

submarine could carry on communication with land stations and airplanes while running fully submerged. A very interesting experiment may be tried out by experimenters who would like to prove this fact. Bury a well-insulated wire in some nearby fairly large body of water, using it as an aerial, and connect up your apparatus in the ordinary way, using the same body of water as a ground. Then use this aerial to prove that it is no different from the aerial you take hours to string up over your roof. Government experts claim that better reception of signals is accom-

plished in some cases than when a regular aerial is used. In the tropics there is a noticeable decrease in atmospheric disturbances when the submerged antennae is used. The outcome of several experiments that are being carried on at the present time will be published in **RADIO WORLD** as soon as they are made public, and some startling news may be expected. The French Government also is carrying on a similar series of tests along the same idea. It is claimed that France has something of vast importance in connection with grounds, which information will be known soon.

How to Put a Vernier Attachment on Your Condensers

By Ortherus Gordon

Figure 1—Home-made vernier attachment which may be applied to any standard make of variable condenser.

RIGHT on the heels of the need for sharp adjustment of radio instruments have come "vernier" attachments for almost everything. Vernier is not a Scotch word, meaning "close"; but the last name of a Frenchman—Pierre Vernier—who first felt the maddening desire for a scale which would measure the fractional parts of a whole unit. He invented what is now known as the "vernier scale." His idea was hailed as a boon by scientists. At the present day a scientific instrument which has any leaning toward accuracy cannot afford to be without a vernier attachment. In fact, some of the verniers are so minute that they carry a magnifying glass around with them for convenience in reading; otherwise the fine points would be lost to the naked eye. Applied to radio apparatus the vernier idea has given manufacturers

a chance to put out some pretty slick articles, especially in the way of variable condensers. But woe to the radio amateur who already has variable condensers without Pierre Vernier's neat device to make them discriminating and set them off! Scrapping perfectly good variables is out of the question—even if in favor of such a desirable feature as the vernier. There is only one attitude the unlucky amateur can take—look glum and stand it, unless he sees some merit in the idea that one radio amateur worked out for the benefit of his own little variable condensers. He wanted a vernier control on his condensers because he knew what close tuning meant. He couldn't afford, however, to buy new instruments. Therefore, being a radio amateur, his thoughts naturally turned toward home construction, and they weren't bent more

than a minute in that direction before he decided that what he wanted was not construction, but reconstruction. In other words, instead of building a whole new condenser he decided to build only the vernier attachment and then find some way to add it to his existing instrument. No sooner said and fretted about than, shortly afterwards, several ways were outlined in which the great idea could be worked out. A little later came definite plans. There it was—the neatest little vernier attachment you ever saw, movable and everything, which could be added to a standard

Figure 3—Assembly of the vernier unit and the standard condenser. The phonograph disc is not put on until completed instrument is mounted on panel.

condenser without danger of putting it out of commission! This article, illustrated by the sketches, tells how the amateur did it. What he wanted was an extra movable blade—not one that turned with the others, but an independent affair, which would swing off by itself when he so desired. He also wanted something that could be operated from the panel and that wouldn't be a disgrace to his bright 3-inch dial.

To fill these requirements he collected, on his workshop bench, an old phonograph-record, one fiber washer, a piece of brass tubing and two new condenser blades—one for the stator and the other for the rotor. The inside diameter of the brass tubing was slightly larger than the outside diameter of the rotor shaft, so that the tubing would fit snugly over it. With these simple parts he proceeded to make the "vernier unit."

When it was finished it looked like Figure 1. The phonograph-record had

Figure 2—Vernier attachment as fitted to the rotor of the standard condenser, also the changes made in the stator of the condenser to accommodate the new unit.

Broadcasting the Yale-Harvard Game

(C. Underwood & Underwood, N. Y.)

The photograph tells the story. In the background is the soundproof booth which overlooked Yale Bowl. In the right foreground, on the overcoat of a newspaper reporter, is reproduced the device by which the cheers could be heard so plainly. Men with reproducers attached to their overcoats were scattered about the huge bowl so that any section that started cheers or songs could be immediately heard by just plugging in at the booth. From the booth the sounds were transmitted by special wire to WEA.F.

Short Waves

By John Kent

The Potentiometer's Work

THE potentiometer produces fine variations of voltage by means of a sliding contact which plays over a fixed resistance through which a constant current flows and which has a certain definite resistance. A clear idea of the potentiometer may be had by taking two circuits, an input and an output, going to and coming from the resistance. The input, which may be a source of emf (electromotive force), goes to the ends of the resistance. The output is taken from one end of the potentiometer and the sliding contact.

Ohm's law states that $E = I \times R$ (Voltage equals amperage times resistance), and since the input circuit is through the whole resistance, I remains constant. The part of the resistance between the variable contact and the end from which the output circuit is taken is variable; hence, since I is constant, in order to maintain the equality of the equation, voltage equals amperage times resistance. If the resistance changes then the voltage must change in the same direction by a proportional amount.

* * *

Try This Method

MANY amateurs like to hook up their own sets. They buy a lot of apparatus, a panel and other devices, then they solder up all the connections and are surprised and disappointed when they don't get the results they expect. Try this: Instead of going ahead and hooking up permanently at once, use some old copper wire and experiment. Then if you don't get satisfactory results, you can change your connections without feeling that you have been stung.

* * *

The Sensitive Spot

IN operating a crystal detector, it often occurs that a sensitive spot usually is lost with the least jar or shaking of the table. To keep a proper balance, adjust your crystal detector to the sensitive spot of reception. Drop some melted wax from the top of a battery onto the covering of the crystal detector. This means that the sensitive spot of the crystal must be covered. The detector will then be grease proof and cannot be knocked out of adjustment.

(Continued from preceding page)

been cut down until it was half an inch larger all around than the dial. The hole in its center had been enlarged and the threaded end of the brass tubing fitted snugly into it. On the other end of the brass tubing, fastened to it by pins riveted over, was a condenser blade. The whole unit, plus a fiber washer, as shown, was slid over the shaft of the rotor so that the new blade fitted closely against the shoulder of the shaft, as shown in the upper part of Figure 2. The "vernier unit" is drawn in with dotted lines.

The shoulder mentioned (S) should be filed, or machined, so that it is the same thickness as the washers which separate the blades, otherwise the corresponding spaces in the stator will have to be widened so that the vernier blade will not touch any of the stationary blades.

In preparing the stator so that it will accommodate the extra "unit" it was only necessary to add a blade, as indicated by the dotted line in the lower part of Figure 2. Mr. Amateur also found it necessary to enlarge the fiber bushing in the cover of the stator so that it would take the increased diameter of the brass tubing. This is also indicated in Figure 2.

The vernier unit made and the stator prepared, everything was ready for assembling. Figure 3 gives an idea of how the condenser was put together again. A fiber washer, just one-half

Figure 4—How the disc of the vernier attachment and the dial of the regular instrument look on the panel. The disc and the dial are not put on until the instrument is set up on the panel.

as thick as the space washers used in the instrument, must be inserted between the vernier blade and the inside of the stator cover, as shown in the sketch. The disc and the dial are not put on until the instrument is set up on the panel. Then both disc and dial go on outside, so that it appears as in Figure 4.

The reconstructed instrument is a beauty. The pins, which are sunk into the phonograph disc, help in the adjustment because, actuated by them, the vernier plate may be turned by the idle fingers while the other movable plates are being turned by the thumb and forefingers.

No dimensions are given in this article. It is the idea itself that is the more important.

Figure 1—General arrangement of the receiving and sending apparatus of 1XM. On the extreme left is shown the 200-watt, quenched-spark transmitter used only as an emergency set and which has a normal working range of 500 miles.

1XM — A Station That Claims High Radio Honors

By C. White, Consulting Engineer

THE Massachusetts Institute of Technology's radio station 1XM, operated by the M. I. T. Radio Society, is one of the most remarkable amateur radio installations in the United States. Its unique design and high operating-efficiency place it in a class by itself. Signals transmitted by this station have been heard many times in Honolulu and very often in Great Britain and Europe. Such results are made possible only by the most careful technical attention to small-design problems, which actually determine the success of a station.

Figure 1 illustrates the general arrangement of the sending and receiv-

ing apparatus. On the extreme left is shown a 200-watt quenched-spark transmitter used only as an emergency set, and which has a normal working range of 500 miles. Next to it is a Signal Corps type of radiophone transmitter and receiver. This outfit is often used for reception. At times, it is employed to broadcast local phone-messages, but its use in this particular field is limited by the local broadcasting stations. The next group of apparatus is an Amrad short-wave receiver, using radio- and audio-frequency amplification. The switch-board panel is unique in operation. It effectively controls the motor-generators and the connections for modulation on the tube transmitter shown on the right.

This transmitter has a normal working range from 3,000 to 6,000 miles! It is creating much attention among radio amateurs. This feat of opera-

tion is really worthy of nation-wide comment, since with only four 50-watt tubes an amateur station can send at a range equal to that of a commercial station using *many times* the power.

For straight C-W, 1000 volts is impressed on the plate circuit of the tubes and the modulation is accomplished by a key through relays on the grid circuit. The carrying power of the 200-meter wave is enormous. The 1000 volts, D-C, for the plate supply, is obtained by a mercury arc rectifier. For work at shorter ranges, the plate-supply voltage is taken directly from the 500-cycle motor-generator. By this method, a characteristic pitch note is produced. Those amateurs who have copied 1XM signals will testify as to the quality of this note.

Figure 3 shows a close-up of the transmitter showing the control panel, key, and relays, tubes, meters, transformers and filters (under table), tun-

Figure 2—Showing the counterpoise which is used for a ground. The low capacity of this system causes a very sharp wave to be radiated.

Figure 3—Close-up of the transmitter showing the control panel, key, and relays, tubes, meters, transformers and tuning coil, also the mercury arc-rectifier. The radiating equipment consists of four wire cage-aerials one hundred feet long.

Try This New Tuning-Coil Hook-up

By Robert L. Dougherty

IN these days, when all you hear talked about in radio is superregeneration, heterodyne, and two-variometer circuits, other elements are overlooked. If one refers to a tuning coil, he is looked at in surprise and, maybe, disgust. But if the average amateur were to be told that he could get regeneration on a three-slide tuning coil, he would turn from disgust to wonder. However, this is just what I am going to try to prove to you in this hook-up.

For the person who is inclined to experiment, or the radioist who would like to have a bulb set but is hindered by lack of ready funds, the little circuit published herewith will prove a pleasant surprise. It is not without its merits. Of course, the results will not be equal to those of a three-unit regenerative set, yet it is surprising what may be accomplished with it after one has become accustomed to its manipulation.

Schematic diagram of hook-up for a three-slide regenerative set. If you happen to have a variable condenser around, you can insert it in the aerial lead. This will make the set more selective, although it is not absolutely necessary for proper manipulation. The new W-D 11 works admirably with this hook-up. It needs only a single dry-cell to operate at its highest efficiency. Long distances have been worked with this set. See what you can do with it—you sceptics and hook-up hounds.

The apparatus needed is a three-slide tuner, a bulb, socket, rheostat, A and B batteries, and phones. When hooked up according to the illustration, and slider No. 1 is moved back and forth—that is, the one controlling the wave length—a sound similar to the “frying noise” in a regular regenerative set will be heard. If this noise is not heard, you will have to adjust slider No. 3. The best position for this slider will generally be found about three fourths of the way along the coil in approximately the same position as that accompanied in the illustration. Slider No. 2 should be used after the signals are heard; but it will be found that it will work best when kept below the position of slider No. 3. After slider No. 3 has been adjusted, it will not be necessary to move it, as all the tuning is now done with Nos. 1 and 2. A variable grid leak is of great assistance in connection with this hookup.

Radio Relays to Remember

By George W. May, R. E.

Topography of Country Effects Range

ONE important element in radio is “the lay of the land”—the topography of the country. It has a great deal to do with the effective range of both the receiving and the transmitting set. Outfits that are exactly alike in their make-up and located only a few hundred feet away, have been known to have widely different ranges. Many times this has been experienced by the average radioman and, some-

times, found hard to explain; for conditions seem to be apparently the same, but close observations will bring to light some little factors that tend to reduce or increase the range of the set.

Many advocates of the open air who take their receiving sets with them, especially when situated in a depression between mountains, may be disappointed when they get poor results or even no results. It is a known fact that radio waves do not descend to any extent into valleys

surrounded by high, steep mountains. If there is a considerable space, this does not hold true; for in this case the radio waves follow more readily the exact contour of the earth's surface. When the mountains are close together, the waves seem to jump from peak to peak rather than descend between them. If you are in the mountains, try and erect your aerial at as high a point as possible. Maybe you happen to be in a location where your signals are poor. Dry, arid land surrounding a radio station also tends to reduce its range, while expanses of water will tend to increase the range. Surroundings of metal often decrease the range. High, steel buildings absorb waves. Whenever you are surrounded by buildings, it is well to suspend your aerial as high as possible.

* * *

Locating the Aerial

WITH the best of conditions, the aerial can be run from one end to the other of the house, inside as well as on the roof, although the outside aerial is recommended as superior to any other. The greater the height at which it can be suspended has some effect on the ability of catching wave trains or signals. We must remember that radio waves go through everything. The plaster on the walls of a house have no effect on radio waves and offer no obstruction to them whatsoever.

(Continued from preceding page)

The radiating equipment consists of four wire cage-aerials 100 feet long, the upper end of the antennae is attached to a 150-foot stack. A counterpoise is used for a ground, and the low capacity of this system causes a very sharp wave to be radiated.

Figure 3 also shows the general appearance of the system and gives a fair conception of the magnitude. The efficiency of the cage-type aerial, as proved by actual tests at this station, is very high.

Aside from the ordinary routine relay of messages, the society conducts an active research and testing cam-

paign. Many of the experiments carried out at this station are of an extreme technical nature. The result of tireless effort has been the development of many new and unique hook-ups.

Figure 3 gives a general idea of the nature of the experimental bench. The ease with which any voltage, A-C or D-C, may be obtained makes it quite easy to conduct any type of test work with the minimum amount of wiring. By diligent application, due to well-founded technical training and experience, this station is maintained and operated at maximum efficiency. New apparatus is constantly being added. An 8-tube superheterodyne was contemplated recently.

Secretary Denby Rates Radio High in Government Work

Naval Service Earns Over Two Million Dollars in Six Years. Aids Merchant Marine, Press, and Governmental Service

By Carl H. Butman

WASHINGTON, D. C. — Radio in the United States Navy, taken solely as a business proposition, is a money maker for the government. During the past six years, \$2,222,956 has been deposited in the United States Treasury out of a far greater amount collected for the transmission of commercial radio messages. The collections during the last fiscal year totaled \$627,904, out of which \$369,735 was deposited in the treasury, Secretary Edwin Denby states in his annual report. Collections in the year 1922-23 showed a falling off of such receipts due to the fact that many merchant ships were laid up, while savings also decreased because all governmental departments were endeavoring to economize in communication expenses.

Governmental traffic handled by Naval Radio stations, other than Naval communications, would have cost \$1,080,800 at commercial rates and was less than a third of the traffic handled the preceding year.

This amount added to the commercial receipts would have brought the year's business in Naval radio traffic to \$1,708,704 in receipts and savings. When it is considered that the Navy in no way competes with commercial stations, but handles messages only where and when commercial stations are not available, the aid rendered in this auxiliary radio work is better appreciated.

For the Merchant Marine alone the Naval Communication Service handled 3,749,483 words during the past year and forwarded press matter to the number of 1,012,279 words.

As a new departure in the interests of economy, an attempt was made, last summer, to employ the Naval radio circuits exclusively for transcontinental traffic, but static interfered in May and June so severely that delays were encountered. Fairly satisfactory results were obtained from transpacific circuits, but the completion of the new high-powered set at Guam is required for efficiency in that circuit. Headquarters of the

European communication service were established at Paris, and of the Asiatic Division at Cavite. In Europe, the Naval Service co-operated with the American Relief Administration and the European Chile Fund. During the Limitation of Arms Conference, two Pacific circuits were set up for the Japanese Government, one of which has been continued for business purposes between the United States and Japanese Governments.

A service rendered by the Navy, but little known, is in receiving S O S calls, which in the winter average thirty a month on the coast between Maine and Cape Hatteras.

Sixteen of the Navy's shore radio stations were closed as "not necessary in accordance with the approved national policies," during the past twelve months. Twelve of the fifty-six radio compass stations, operated by the Navy free for the benefit of merchant vessels lost in fog or without efficient compasses, may have to be eliminated due to lack of personnel, it is stated by Secretary Denby. He explains that the furnishing of compass bearings to vessels off the Coasts and on the Great Lakes is of great value to shipping interests. Some stations handle as many as fifty calls a day in bad weather.

At present these stations operate on an 800-meter wave and are efficient for a range up to 150 miles, but a new long-wave radio compass is being developed which will operate on waves between 500 and 2,500 meters. This would increase the distance of audibility up to about 1,000 miles. In addition, it is expected that this instrument will have great value in time of war.

A new Naval radio-set for use in spotting gun fire was tested out at the Anacostia Naval Air Station recently. After a fifteen-hour flight-test with the manufacturer's model of the SE-1375 spotting plane set, the model was returned to the manufacturers as a guide for production of a number of sets. It is reported to have stood up well under the test and, with the exception of a few minor changes, to have given very satisfactory results.

Roughing It By Radio

(Cartoon by Lawrence B. Hinckley)

Accurate Tuning with the Capacity Switch

By Donald Van Wyck

THE desire to place all controlling elements of a cabinet radio-receiving set on the outside of the panel has brought into general use the series parallel-switch. The suggestion that additional instruments be provided for the receiving set in order to increase selectivity is usually accompanied by groans from the man who pays the bills. But when incorporated in the outfit they may be rearranged to advantage.

The rearrangement consists chiefly in reconnecting the primary condenser so that its sphere of usefulness is considerably increased. By the shifting of a few wires and the addition of a single-switch knob,

Figure 1. How the switch will look when completed and laid out on the panel.

the goal is achieved. The effect on the radio enthusiast when another switch is added depends entirely on his status in the radio field. The newcomer who scarcely knows the controls feels that he never will be able to tune in the set properly.

The amateur out in the country where open space is not at a premium generally erects an aerial of 200 feet or more. No doubt he believes that a long aerial will produce signals of greater strength; but he fails to consider that radio-phone broadcasting, in which he is most interested, is sent on a wave of 360 or 400 meters, whereas his aerial has a fundamental wavelength of, maybe, 450 meters or more, or is probably very short.

With this in view, the only possible move is to insert some capacity switch and capacity in series, or parallel, with the aerial. The aerial is like a huge conductor with the earth as the other conductor and the air between as an insulator, or dielectric. Thus, by placing a condenser in series with the aerial, it will produce an effect similar to two condensers in series.

The primary condenser of radio-receiving sets is usually connected

Figure 2—A completed knob made from a wooden spool.

in series with either the ground or the antenna lead. When it is in this position, it enables the desired fine tuning, but does so by simultaneously shortening the natural period of the antenna system comprising antenna and ground leads and the primary inductance.

While this reducing is permissible with the antenna and variable condensers in use, it nevertheless lowers the effective tuning of the set as a whole. The series variable condenser makes the tuning of the receiving set more difficult.

With the variable condenser placed in series with the primary inductance, tuning may be said to be more complex because the condenser unit must be set within certain limits depending on the wave length to be received. This with the primary fine and coarse switches makes three controls which must be set in correct relation to one another. When the primary condenser is connected in parallel to the primary coil the condenser dial may remain at zero during the preliminary tuning with the switches, and, later, may be utilized as a corrective tuning measure. This latter arrangement also increases the wave length to which apparatus may be tuned.

There is no doubt that both series and parallel switches have their advantage, the former for the lower and the latter for the longer wavelengths possible with each particular outfit. This series parallel-switch then answers the purpose. This switch has puzzled many radio amateurs who are puzzled when they realize its complications. The double switch-arm has also served to confuse the casual inspector because he labors under the impression that it is necessary to bring flexible leads to each of these metal strips or else he thought that both arms were separate pieces of sheet metal. Yet the series parallel-switch is nothing more than two separate contact arms. It is simpler to construct your own capacity switch than to go out and purchase one. The parts of a capacity

Figure 3—Schematic diagram showing how to hook-up apparatus for a series-parallel switch.

switch consist of spring sheet-brass, a switch knob, and 8 contact points. The knob may be made at home from a piece of hard wood or hard rubber, or it may be made from a large-size thread spool sawed radially in half.

Two contact arms are cut from the sheet brass in the shape shown. The distance from end to end may not exceed 3 inches, and may be less, depending on the amount of available space. From each end, bend the strip at right angles about $\frac{1}{8}$ of an inch from the end. The two metal arms are screwed to the knob on the large, or under, side by small wood screws. The spacing between the two blades is such that there is at least $\frac{1}{8}$ of an inch to separate the two inside edges, and that the cut-out portions at the center may not touch the machine screw which holds the knob in place. The eight contact points for the switch are placed four on each side of the center along the arc traversed by the ends of the switch arms. The spacing between the points is determined by the switch blades and should be such that the blades rest squarely upon the faces of the contacts in each position. The contact points should be neatly placed with reference to the center line of the switch knob so that the appearance of the panel may be enhanced rather than spoiled. The accompanying diagram shows the wiring circuit of the capacity switch. The condenser for this purpose should be about 43 plates, although a smaller size will do.

In general, the switch is placed in the series position for tuning in short wave-lengths and in parallel when tuning in the longer wave-lengths. Usually this switch is used with the honeycomb type receivers, although it may be used with most any type set made to-day.

The Radio Primer

Are Coming into Radio Circles

Weekly A B C of Radio Facts and Principles Fully and Tersely Explained

By Lynn Brooks

HOW are electric currents produced?

Electric currents are produced in several ways, the two most important being by electromagnetic induction (magneto and dynamo), and by chemical action. Electric currents are moving electrons. These electrons move along a wire, thus producing the current with which we are most familiar. They may also move

Figure 2—The sum of the currents passing through a, b, and c is equal to the sum of the currents passing through d and e. Each sum is equal to the current passing through any part of the single wire, as at g.

unattached through space from one point to another. This is what happens when a flash of lightning occurs. It is what occurs in the X-ray bulb and in vacuum tubes used in radiotelegraphy. They may move also through a liquid or gas. This is what happens when we use an electric current to electroplate objects—as, for instance, silver-plating spoons.

* * *

What has a circuit to do with conductors?

A circuit is a number of conductors arranged so that they are connected electrically. A current of electricity will flow through a circuit when some source of electric current is attached to the circuit. When a current is flowing in a circuit the current is of equal strength in all parts of the circuit, provided the circuit consists of only one path.

* * *

Will the current be the same when flowing through the circuit, as shown in Figure 1?

The current going through the resistance—R—the current going through the telephone receiver, and the current going through the telephone

Figure 1—Diagram of electric circuit with resistance, telephones, and transmitter in the circuit. The electric current is equal in each unit.

transmitter are equal. If the circuit is divided then the sum of the currents passing through the divisions are equal.

* * *

How are the currents in Figure 2 divided?

The sum of the currents passing through A, B and C are equal to the sum of the currents passing through D and E. Each sum, of course, is equal to the current passing through any part of the single wire, as at G.

* * *

Will an electric current produce magnetism?

A current is recognized by the effect it produces. An electric current will cause magnetism, give rise to heat, cause chemical action, and may be made to operate by using the magnetic effect.

* * *

What have we learned?

We have learned that magnetism is produced by an electric current; that a moving electron is surrounded by a magnetic field; that the magnetic field is made up of magnetic lines of force; that the direction of the magnetic lines of force is the direction along which the north pole of the magnet is urged.

* * *

What is the magnetic circuit?

The magnetic circuit is the path which the magnetic lines of force follow in going from the north to the south pole of the magnet. It has been found that iron is the only perfect conductor of these magnetic lines of force.

* * *

What does iron contain?

Iron is said to have permeability be-

How to Treat Phones

By John Kent

IF the owners of receiving sets would realize what delicate instruments the headphones are, we wouldn't hear so many complaints that they are not getting as good results as they did the first few weeks their set was in operation.

You wouldn't expect your ears to be as perfect as they are if you gave them half the abuse that the average headphone gets during its life.

Here are some of the things you shouldn't do to a pair of phones:

Don't open the phones (take off the ear caps), or let anybody else do so unless you know just what you are about.

Don't tap on the diaphragms. They are easily bent and dented.

Don't drop them. They may not break; but any jar lessens the magnetism in the permanent magnets, thereby lessening their sensitiveness.

Don't pull the phones out by the cord. It is only tinsel.

Don't set them in a place where they are liable to get damp or wet.

DON'T TEST BATTERIES with a pair of good phones. You are liable to burn them out. Most phones are wound with No. 40 wire which is as fine as a hair and is not meant to stand heavy voltages.

Aerial Connections

By George W. May, R. E.

LEAD-IN wires to the receiver may be connected to the end of the aerial or to the center. If connected at the end, it then becomes what is known as an inverted aerial. If connected at the center of the aerial it becomes a T aerial. This type aerial has a tendency to reduce the wave length approximately one-half that of the inverted L aerial. In case the aerial is constructed on the roof or outside the house, it is advisable to carefully insulate the lead-in wire by running a porcelain tube through the window casing or some other part of the house. This is not absolutely necessary in dry weather; but when the wood gets wet, it becomes a good conductor and may cause trouble as a result of electrical leakage through moisture.

cause it will carry lines of force. Different kinds of iron have different degrees of permeability; therefore, certain kinds of iron will carry more magnetic lines of force than others. Wrought iron has a very large permeability. All other substances are poor conductors of magnetic lines of force.

National Radio Week—Dec. 23 to 30

Are You Ready for this Big Event?

NEXT WEEK, beginning at dawn on Saturday, December 23, and ending at midnight on Saturday, December 30, is National Radio Week.

It is the first National Radio Week in the history of this important and wonderful new science.

It will be celebrated all over the United States, Canada, and Cuba.

It comes at a time of the year—Christmas and New Year's—when all the civilized world is alive with gaiety—filled with the desire to do good and bring cheer to others.

And, this year, in no other way can the people give or receive cheer so well as through radio.

It is new! You who are dyed-in-the-wool fans know its joys and surprises. Those yet uninitiated are anxious to know—to "listen in."

It is estimated that there are six million radio fans in the United States. How many others want to be fans?

You can help them to become fans. By doing so, you help radio.

What can you do? you ask.

Hold block parties—the good old-fashioned kind—substituting radiophone music for bands.

Have radio parties—invite all your friends—and get the "kick" out of the air.

If there are any radio "knockers," prove to them that radio has come to stay.

Improve your set. See what distance you can get out

of it and communicate with everybody you hear at any great distance.

Boost radio to your friends who have no sets.

If you have a radiophone transmitter, coöperate with the neighbors by transmitting for their benefit. Get acquainted with them. Help them to become fans.

If you have a spark station, try to help out by transmitting only when necessary. Cut out talking to the fellow on the next block just to hear your spark working.

If you can play any instrument—outside of a receiving set, of course—apply to your nearest broadcasting station and offer your services. They will be glad to have you.

You Old Timers! Get acquainted with the little fellows. Show them what they can do with a little time and patience. You had to be taught first.

You Experimenters! Try out new ideas. Everybody is looking for them. And you may strike something big.

See if the pastor of your local church wouldn't like to have you install your set for a couple of nights and give small radio recitals from the broadcasting stations.

Interest the merchants in your locality. Maybe they don't realize that they are letting a good thing get by them.

In any event, celebrate National Radio Week and be a National Radio Week booster!

Radio Rules for the Day, Week and Month

MANY who own radio sets believe that once the sets are in working order and bring in signals, the only thing left to do is to watch the batteries. A radio set isn't like an egg—it improves with age. A radio set needs looking over once in a while. Dust is an enemy of radio, because it generally forms a short circuit.

Aboard ship there are certain things that are part of the daily routine that must be done. They serve to illustrate the care that should be taken with a radio set. Here is a set of rules to follow:

Daily

1. Wipe off all instruments carefully with chamois skin or a very soft cloth.

2. Examine contacts of all receiving circuits and remove dirt and corrosion.

3. If using crystal detector, clean by immersing in bisulphide of carbon.

4. Clean spark-gap and transmitting apparatus. Inspect all transmission leads both on the back and front of board.

Weekly

1. Rub all moving parts lightly with vaseline. Blow out variable

condensers to remove particles of dust that may collect between plates.

2. Clean transmitting condensers and inspect the connections.

3. Clean key contacts and dress down with a light filing, if found to be pitted.

4. Rub the antennae switch blades lightly and see that the clamps are making good contact.

Monthly

1. Test and charge storage batteries. See that the solution is clean by use of hydrometer.

2. Make note of any deviation in the operation of any of the instruments and file same with the head of the department.

3. Inspect antenna connections and wipe off all insulators with stiff brush dipped in carbon bisulphide.

Factors That Effect the Range of Radio Transmission

By *B. R. Cummins*

Radio Engineer, General Electric Company.

ONE of the questions almost invariably asked regarding a radio transmitter is, "How far will it send?" This question is justifiable. It has become standard practice with builders of radio-transmitting equipment to carefully specify the conditions under which any guaranteed ranges can be made. Even then it is seldom that a conservative company will guarantee transmission at all times.

In the first place, a radio transmitter will transmit several times as far at night as in daylight; it will transmit farther on a dark night than on a moonlight night. This is due to the fact that sunlight and moonlight causes an ionization of the atmosphere, which results in much greater losses than occur when such ionization is not present. The greatest ranges are obtained when the atmosphere between the transmitting and receiving stations is most nearly a perfect insulator.

The range depends on the nature of the territory lying between the transmitting and receiving stations, the greatest ranges for a given power usually being obtained over water. Any metal, particularly iron or steel, lying between the stations will cause a loss of signal strength. Such metal may either be in the form of artificial structures such as buildings or building frameworks, or may be in the form of ore deposits. Some sections of the country are noted for their poor location for radio reception, and the cause of this can usually be traced to this reason.

In many places it is possible to receive effectively from all directions but one, and it is usually found that in this direction a metallic structure, or a metal deposit, is responsible for the lack of reception.

A radio station which can be depended upon for reliable communication, through the winter months, for a given range can only work effectively during the summer months over a fraction of this range, assuming that the power of the transmitter is not increased. This is not due to any diminution of signal strength, but to the percentage presence of so-called static disturbances during the summer months. Static disturbances, which result in cracking, hissing, or grinding noises

in the receiver head-phones—frequently sufficient to make this radio signal unintelligible—have been the subject of investigation and analysis for many years, during which time many attempts have been made to determine their origin and means for preventing their detrimental effect on radio reception. While some very special receiving-equipment and antenna systems have been devised to increase the ratio of signal strength to static strength (the so-called "signal-static ratio"), the most positive way of overcoming static seems to lie in transmitting sufficient power to make the radio signals intelligible even in the presence of static. This was the procedure followed, for example, at the Lafayette Station in Bordeaux, France, built by the United States Navy Department during the World War, for reliable communication if transatlantic cables were cut by the enemy. This station has a capacity of 1,200 kilowatts.

The range depends, also, on the type of receiving equipment which is used and the ability of the operator to use his equipment to the best advantage. A receiver with one or more stages of amplification will receive stations which cannot be heard without such amplification. There is a limit to the extent to which amplification can be used. It does not serve, for example, to overcome static disturbances, because such disturbances are amplified to the same extent as the radio signal itself, leaving the signal-static ratio the same and, therefore, not making the message any more intelligible.

The wave length at which transmission is carried on is also an important factor in the range of a given power. Energy radiated at short wave-lengths is absorbed to a much greater extent than energy at longer wave-lengths. For this reason, very long wave-lengths, comparatively, are usually used for a long distance such as transoceanic communication.

The personal equation of the receiving operator is of importance. Signals which are quite readable to some operators are absolutely unintelligible to others.

The number of stations working in close proximity also decrease ranges which would otherwise be

obtainable; for many signals which have sufficient strength to be easily interpreted are made unreadable by interference caused by other stations.

In general, therefore, in specifying the range of a radio transmitter, it is necessary to specify whether transmission will be carried on by day or night; in winter or summer; the type of receiver, and the amount of amplification; the nature of the country lying between the transmitting and receiving stations; whether or not uninterrupted communication is required or whether so-called "deferred service" is satisfactory; the wave length on which transmission will be carried on; the kind of transmission desired, that is, telephony, continuous wave telegraphy or interrupted continuous wave telegraphy; the vicinity in which the transmitter will be located with respect to other transmitters; and, lastly, but by no means of least importance, whether or not the range specified, even after the foregoing conditions are known, shall be a conservative one or the maximum expected.

It is impossible, in a very brief discussion, to analyze more fully the various factors entering into range considerations which have been enumerated; but the mere mentioning of the existence of these factors should be sufficient to make all of us realize that a brief statement to the effect that a radio transmitter has a range of, say, 500 miles, is practically meaningless.

This does not mean that reliable communication cannot be carried on over given distances, for a careful consideration of all conditions will permit satisfactory equipment being installed. Such equipment will frequently transmit distances far greater than the rated range of the set. For example, a transmitter manufactured by the General Electric Company which is rated, under definite conditions, at 175 miles, has recently communicated by telephone over a distance of 4,050 miles.

In view of the foregoing, anyone concerned in the range of radio stations should assure himself of the conditions under which the transmission has been, or is to be carried on, before arriving at any definite conclusions.

Remote Logging Camps on Pacific Coast Get News Daily by Radio

WASHINGTON, D. C.—The spirit and morale of the logger, situated far within the fastnesses of the great Pacific Coast forests, has been materially improved since the installation of modern radio-receiving sets in logging camps. Many of the western newspaper broadcasts carry the daily news of the world into the heart of our lumbering districts where their daily papers do not reach and the telephone is not available.

Instead of waiting a month to learn of some event in the outside world, the logger gets press dispatches daily. Thanks to radio, he is no longer a backwoodsman, in the old sense of the word. He received the news referring to the President's message on the Ship Subsidy Bill and the final score of the Army and Navy football game almost as soon as the city radio fan.

Forest Workers Get Forty Stations

"With modern apparatus of the vacuum tube type, the logger can tune in on no less than forty broadcasting stations from Calgary to Los Angeles, and from Denver to Portland," according to the National Lumber Manufacturer's Association, whose research department has been devoting considerable time to the use of radio. Up in the forest-clad hills of Oregon, far from the railroad and mail routes, a digest of the daily news or a concert from San Francisco, "listens pretty good," as one logger put it.

The logger's radio set has a more important use than its recreational value, however; it is a business asset in the remaining big timber stands of the country. Through the aid of the fleet of airplanes, assigned to forest-fire observation by Major General Patrick, of the Army Air Service, each of which is equipped with sending and receiving radio, conflagrations in the districts patrolled have lessened notably.

Co-operating with federal, state, and private forest-protection, high-flying airplanes cover more territory in a day than a forest ranger on foot could cover in three months. "Spotting" a fire, or smoke, the plane hovers over the site while the observer plots the location on a map and then broadcasts a fire warning giving the location. Station operators equipped with receiving apparatus catch the air scout's message and relay it, usually by private phone lines, to the ranger or patrol station nearest the fire, and within a few minutes detachments of skilled fire-fighters are enroute to the section in danger. Since speed is so essential in

By Carl B. Hawes

(Photo by National Lumber Mfrs. Assn.) Loggers of to-day are enjoying radio as much as city fans. "High-Climbers" crawl to the upper branches of trees 300 feet high to ring the aeriels, carrying axes to trim branches as well as a line by which the aerial is hoisted.

fighting forest fires, first the airplane, and now radio, won the respect of the owners and operators of timber lands.

Radio also serves to anticipate the approach of lightning storms and to approximate their intensity by means of a static barrage which might be called a "radio lightning recorder." This consists, the Lumber Association states, of a movable loop-antenna which rotates about a vertical shaft, not unlike a radio compass. By turning the loop parallel to the general direction of the oncoming storm, the direction of approach may be determined with an error of less than four degrees, as the static discharge is at its maximum when the loop is parallel to the line of approach.

Radio Lightning Detectors

The purpose of learning the direction of the storm is to enable the members of the patrol to plot its course and send out observers to locate trees struck by lightning. Lightning is said to cause twenty-five per cent of forest fires, and its particular hazard lies in the fact that unseen bolts strike trees

and smolder for days before actually breaking into flames.

The static barrage, the latest of radio fire-fighting equipment, has been operated quite successfully. Technically it measures the frequency of the static discharge and records it on a dial or indicates it visibly across a spark gap. When the frequency of the discharge becomes excessive an automatic electric gong is rung to announce impending danger. The direction of the storm is then determined by means of the radio loop, and by the time lightning is flashing over the stands of timber, patrols have started through the threatened district, alert to spot trees struck by lightning.

Many of the forest wireless stations are manned by ambitious young amateurs, some of them owning their sets, and all of them seeking to do constructive radio work and perfect their knowledge. One privately owned receiving set is reported to have picked up accurately messages from four airplane patrol routes miles apart.

Lofty Aeriels, 200 Feet High

City amateurs who boast of thirty-foot aerial masts, would be envious of the natural masts available in the western forests, where giant fir trees tower three hundred feet. At least they would be envious until they began to wonder how to utilize this excessive height for stringing an aerial. On the camp's "high-climber" evolves the job of rigging the lofty antenna. He is skilled in climbing tall trees, as part of the logging business demands daily trips aloft to oil pulley blocks for cables or to prepare a new setting for the yardage operation. By skillful manipulation of a single loop of rope about his waist and around the bole of the tree, the high climber, equipped with a pair of leg-irons, or spurs, slowly raises himself upward. With a deft twist of his wrist, he flips the rope upward a foot or two at a time, trusting his weight to it while he replants his leg irons a little higher on the trunk. It is a task the city-aerial builder would not relish. It requires unusual skill and steady nerve on the part of the climber; but that veteran thinks nothing of it.

Foresters and lumbermen say that, in the Pacific Coast timber-belt, radio has accomplished, within a few months, what would otherwise have taken decades to bring about. It has become a permanent fixture tending to promote both contentment and efficiency, as well as to afford a means of fire protection of hitherto undreamed-of worth.

Radiograms

The Latest Important Radio News Briefly Told for the Growing Army of Radio Fans

PRESIDENT HARDING'S message to Congress was successfully broadcast from NOF, Anacostia, D. C., on Tuesday, December 5. A full-page photograph showing a similar broadcast was published in RADIO WORLD, No. 37, dated December 9, the Christmas Number. Broadcasting the President's address will always be an important radio event. Three separate telephone-wire circuits carry his voice from the Capitol to the Naval broadcasting station NOF. The transmitter which picks up the President's voice on the platform in the House is part of the public-address system recently installed to carry the voices of speakers to all parts of the Capitol. This transmitter is connected to NOF by three wire circuits. The Chesapeake and Potomac Telephone Company has provided three circuits to insure against any possible interruption. One circuit will be used for conveying the President's voice, a second will be used by the engineers as an "order wire" over which they can direct operators and keep the transmitter at an even pitch. The third circuit is provided in case anything happens to either of the others. These telephone circuits are extremely important and without the greatest skill on the part of the local telephone engineers, the President's speech could not be broadcasted directly from the Capitol.

A new radio-receiving set has been installed at the Government's Hospital for the Insane, Anacostia, D. C., by the Department of the Interior. The set has a receiving range of about 750 miles and enables the inmates to receive concerts every evening from many different sending stations.

Domestic exports of radio apparatus during the month of October totaled \$207,535 and weighed 114,309 pounds, according to figures compiled by the Department of Commerce. The value of these radio shipments was as follows: England, \$70,391; Quebec and Ontario, \$35,728; Argentine, \$32,092; Brazil, \$27,072; Japan, \$11,299.

The first broadcast of the War Department was transmitted from NOF Monday evening, December 4, on 412 meters. It was a speech on the Muscle Shoals Nitrate Plant.

The Weather Bureau advises in connection with a recent hurricane which occurred in the Yucatan Channel and southern Gulf of Mexico that the warnings issued by the Weather Bureau were promptly received by cable and by Swan Island (US). These messages were broadcast by radio and by notices to mariners as fast as received by the Panama Canal office. They were instrumental in causing some of the boats in

the New Orleans trade to postpone their sailings for a day or two. The canal and shipping interests appreciate the prompt service given by Forecaster Mitchell and the Swan Island radio station.

The world's record for long-distance radio transmission was broken on November 5, when President Harding's message to the world was received in practically every country of importance on the face of the earth. It was heard even in New Zealand, 10,000 miles away. The message was transmitted from Radio Central, the station at Port Jefferson, L. I., designated for international radio communication.

Morris Keyser, of Philadelphia, recently heard a spoken voice without an ear trumpet for the first time in twenty-seven years. A week before he heard music for the first time on a receiving set, using headphones. He believes that radio has stimulated his hearing so that he will eventually catch sound without any artificial help.

The first detailed report to reach New York City of the rescue of the steamer "Monte Grappa's" crew of forty-five men in midatlantic by the White Star lines, "Pittsburgh," again puts another medal on the breast of the never sleeping radio.

The "Monte Grappa," a new 10,000-ton ship belonging to the Navigazione Libera Trestina, with a cargo of 9,200 tons of grain, was bound from Montreal to Venice. She left Montreal on November 5, under the command of Captain Stefano Bartoli. On Sunday, November 12, she ran into a heavy southerly gale. Her cargo shifted and the ship took a heavy list to port.

Fearing his ship would roll over, or sink, Captain Bartoli ordered an S O S sent out at 7 a. m. Tuesday. His position was given as 43 degrees, 18 minutes north; 41 degrees, 55 minutes west. This call was picked up by the "Pittsburgh," and Captain Jones, after plotting his own position, found he was 185 miles from the "Monte Grappa." Radio communication was kept up during the day.

Captains of deep-sea vessels are requested to report the date when ice and other obstructions reported by radio from ship to ship are sighted. Many reports of this kind come to the Hydrographic Office of the Navy Department bearing only the date of the radiogram and lacking the date when the obstruction was seen. Co-operation in supplying this additional fact will be thankfully appreciated by the United States authorities.

Weather bulletins, forecasts, and storm warnings are now broadcast from the Naval radio stations at Key West, Florida, and Point Isabel, Texas, by continuous wave (arc) instead of by spark, on the following schedules: Key West (NAR), 10 p. m., (seventy-fifth meridian time); wave length, 5,700 meters. Point Isabel (NAY), midnight, noon, and 7 p. m. (seventy-fifth meridian time); wave length, 5,000 meters.

An applicant for radio operator's license was barred from being examined, for a period of six months, on account of having used a false name in his examination papers. Anyone making false statements in applying for examination will be likewise treated.

The French wireless company, "La Compagnie Generale de Telegraphie Sans Fil," recently founded a subsidiary radio company to operate under the name of "Radio-Orient." It has started radio communications with Syria, Lebanon, and most of the European countries.

The decree of May 31, 1921, prohibiting the operation of radio of foreign ships in Swedish territorial waters within 10 miles (nautical) of a coastal radio station is being strictly enforced. The only exception to this rule is in cases of great urgency or where the safety of the ship is concerned. Under the same decree, foreign ships in Swedish harbors may not receive radio messages without permission of the telegraph directorate.

The general call signal WWAA has been assigned for all vessels operated and controlled by the Radio Corporation of America. This general call signal will be used by R. C. A. ships or coast stations desiring to ascertain whether there is an R. C. A. ship within range, and any R. C. A. vessel hearing another ship or coast station calling WWAA should answer.

Mr. Grouch's Radio in Danger!

(Cartoon by Lawrence B. Hinckley)

Radio and the Woman

Crystal D. Tector Says that the Women of the Country Will Be Heard from During National Radio Week

A WEEK from next Saturday—December 23 to be exact—and the first National Radio Week will have started. May it be a great and glorious success from every point of view! May every city and hamlet in the United States and Canada and Cuba—and even in Mexico, where radio is beginning to get a foothold—celebrate it in a thoroughly fitting manner. May it be the forerunner of an annual event that will be looked for by every true American—just as is the Fourth of July or Christmas or any other happy season.

* * *

I KNOW that the women of the country are going to be heard from. In fact, I can truthfully say that my radio sisters have expressed the genuine radio spirit and have planned and built in a manner far beyond my wildest dreams. I told the editors of RADIO WORLD that we would not be lacking in interest and in willingness to work. We will do our share and do it with a thoroughness that will make our place in radio equally as important as that held by the sterner sex.

* * *

THE holiday spirit has begun to entirely envelop this big and breezy city. New York is completely permeated with radio. In every shop there seems to be something with a radio flavor—even to radio hats and radio perfumes. And most everyone seems to be either putting in a radio set or wanting to do so. Most every woman I meet seems to have the radio fever. It is quite the thing for a woman to say that she is able to work her own set. In fact, going up town in a Fifth avenue bus, the other day, I heard two pretty young misses talking in radio terms in a manner that would have floored an expert.

AND I know of several families who are clubbing together to purchase sets. The alleged edict of selfish landlords does not seem to bother much, for excellent results are now obtained from indoor aerials. In fact, David Saranoff, vice-president of the Radio Corporation of America, recently sent messages to England, France, Germany and Norway, and received answers on an indoor aerial. Some of the loop affairs that I have seen are very handsome and would look well in a sitting room or parlor.

* * *

THE women of the "upper ten" are having their sets made to match certain effects of their furnishings, for radio parties are something of a vogue in New York this winter. I have seen several indoor affairs—and have heard of others—that were broadly extravagant in finish and coloring—some even being silver mounted. Of course, such sets are only for those who can afford them, and do not enhance reception to any extent; and I simply mention them to show how the craze is spreading.

* * *

ONE does not need an extravagant set. The best results are obtained from sets that are well made and, above all well managed. The thing is to know your set. One gets better results from a motor car, a watch, a cooking stove, or any other commodity if one really knows it. So to every woman who contemplates owning a set I say, "Learn to know it," and you will be surprised at the results that will follow. Study it as you would study a child and you will find that it will be the greatest source of joy you can imagine. You can not install a set and start it going like a phonograph. It isn't that sort of mechanism. Take time—and know it inside out.

Radio Penetrates Fog

What Is Being Done by Lighthouse Service to Safeguard Shipping

THE greatest peril to shipping is fog. Until recently the captain of a ship has had no practicable means of accurately locating in a fog either his own ship or other ships which he is meeting. The radio fog-signal and radio compass give the navigator accurate bearings in fog just as well as in clear weather. In his annual report to Secretary Hoover, the Commissioner of Lighthouses states that several additional radio fog-signals have been installed during the past year, including one on the new lightship off Cape Hatteras, and one on San Francisco lightship.

The United States now has five such stations regularly in operation, and six more will be installed in the near future. The United States is in advance of any other nation in the establishment of these protective signals.

The lightships are the outermost signal stations of the country, many of them being anchored in the open sea, miles off the coast. Arrangement has been made this year between the Navy and Commerce Departments, for the Lighthouse Service to take over the radio communication equipment on the lightships, placed there mostly during the World War. Hereafter regular radio-service will be maintained with twenty of the outside lightships off the Atlantic, Gulf and Pacific Coasts; this will be of great value both in safeguarding and operating the lightships themselves, and in reporting the needs of other vessels, or of boats in distress. Provision is being made to receive radio broadcasting on these and other isolated vessels of the Lighthouse Service, and radio telephones are being tested for remote lighthouses.

A Quebec Guide Listens In

THE following letter was recently received by the General Electric Co.:

"WGY, Schenectady General Store, New York State, Sir:

i am gide for hunter man wot come at dis place Lac-des isle for hunting deer. dese hunter man bring it wit him a machine for heer you spik sunday nite also tuesday nite i heer song about my old modder dats long tim i dont see my modder and i tink dats dame fine song also i heer oder song i dont no de nam. tuesday nite storie for de small boy and girl bout mak de star shine for dem if dey is good boy and girl. hunter man laff lik hell an tole me ax you how we mak some moon shine.

i hear you spike jus de same lik your at me place i ting you have good machine i lissen more nex week.

tank you and much oblige
gide Camille Poirier
Chemis P. O., Quebec, Canada"

Listen In—Then Write

RADIO WORLD has received a letter from a reader—a member of a radio club—who puts forth a little idea that, to our way of thinking, is a fine stunt. The letter is as follows:

"We have a small club of listeners and very often hear fellows in other States. We think it would be a good idea if, when anybody else hears a station, he would write and tell him about it. By doing so, we can get and exchange little helpful hints and ideas. It is always a pleasure to know that one is heard in other States and cities.

"We ask anyone reading this in RADIO WORLD to write us and start the ball rolling. "Listen in—then write!"—Charles Doherty, 746 Howard avenue, Bridgeport, Connecticut.

Said It with Letters

Hook-up in Radio World Brings Mail too Big to Handle

IN RADIO WORLD No. 30, dated October 21, there appeared a hook-up of a single-coil receiver designed by Mr. W. Miller, Southern Methodist University, Dallas, Texas, with an invitation to amateurs who delight in experimenting to give it a try-out. That the invitation was heeded—and that there is a keen interest in hook-ups that are new and original—is attested by the following letter from Mr. Miller:

Box 222, S. M. U., Dallas, Texas.
December 1, 1922.

Editor, Radio World:

Since you published a diagram of my circuit, in your issue No. 30, I have been snowed under with mail. Inasmuch as I am a student, I cannot reply individually.

I have received over 1,500 requests for further information, description, panel lay-out, and many other things—and I would like to know if you are in a position to publish the matter.

Yours very truly,

(Signed)

W. MILLER.

Are there other radioists who have original hook-ups they would like to have published, so that the vast army of radio fans may have a chance at them? If so, it is evident that RADIO WORLD is the publication through which to present them. It would be interesting to learn how many fans *did not* write to Mr. Miller.

To many anxious inquirers: **RADIO WORLD** has no free list. One copy is sent as a voucher to each advertiser or advertising agent represented in current issues. All other copies are paid for on subscription or through the news trade.

Latest Photographs of the Week Sho

(C. P. & A. Photos)

(Left) The radio broadcasting apparatus recently installed in the rectory of Calvary Baptist Church, New York City. This is the church over which the Reverend John Roach Straton, the militant pastor, presides. Dr. Straton has joined the ranks of ministers who believe in reaching as large an audience as possible and realize that the only way to do so successfully is by radio. As will be seen from close study, Calvary Church possesses a pretty powerful transmitting set. Dr. Straton decided that his sermons—particularly those regarding the Ku Klux Klan—were being heeded by many people outside his own parish, so he had the transmitting set installed that all who wish may hear. An expert operator and staff are in charge of the set.

(C. Fotograms)

(Above) Lieutenant Elmer I. Oliphant, one of the gridiron's gr who played with the United States Army team, now director education at Union College, New York, is shown here giving a new football rules at the WGY broadcasting station of the Gen Company at Schenectady, New York. As will be seen, Lieutenant is talking directly at a microphone—the small circular-shaped ob of him. This picture gives an excellent idea of how one should talking for broadcasting—in a perfectly natural position about half from the microphone. Then speak clearly and naturally.

(C. Underwood & Underwood)

(Above) Dr. Albert Abrams, noted pathologist, who is now on the Pacific Coast, demonstrated his little "radio love detector," or, scientifically called, "electronic energy detector." This shows, right to left, Joseph O'Connor, radio expert, Dr. Wirklich, and Miss Ruth Rittman and (seated with glasses) Dr. Albert Abrams, holding a test of the machine. The young lady, a nurse, wished to know if she was in love. Dr. Abrams told her to concentrate and he then placed a glass electrode connected with the "detector" over her heart. The radio machine hummed and told the story—she was very much in love.

(C. Kadel & Herbert)

How Radio Put to Startling New Uses

(C. Wide World Photos)

(Above) Thomas Donnelly and J. H. Jenkins, prominent clubmen of Chicago, have equipped a radio station atop the roof of the Drake Hotel. They spend their spare time transmitting concerts with a normal radius of 1,200 miles. They assume all expense and pay prominent stars to sing or play for the benefit of radio fans. Messrs. Donnelly and Jenkins have a novel arrangement of "plugging in" on any of the hotel ballrooms, thereby being able to broadcast all other concerts given at the hotel, aside from their own. They are known to "fans" as WDAP and 9XA. The photograph shows Mr. Jenkins and Ralph Shugart at work transmitting.

(C. Underwood & Underwood)

(Above) Did you hear the cheers when Princeton defeated Yale and Harvard, and Yale defeated Harvard, during the recent football season? Did you hear the Army and Navy boys sing during their recent thrilling game? This is one of the devices that brought these effects to you and permitted you to hear them as plainly as if you were right there in a front seat. The microphone, that cylindrical object so clearly shown in this photograph, is a wonderful thing. No sound is too insignificant for it to catch. It performs its task with accuracy and precision. It has helped to give outdoor sports a world-wide range of interest.

(Small picture below) Radio is now used as an aid in securing recruits for the United States Army. The photograph shows Sergeant George Kline with his home-made radio set which he rigged up on the roof of a skyscraper near City Hall Park, New York City. Assigned to the duty of securing recruits for the Army, he decided on this novel scheme. And it may be said to his credit that he has already recruited several dozen men who, otherwise, might not have given their services to their country. Sergeant Kline's set, while a home-made affair, is simple and effective. He is a pioneer among radio enthusiasts.

(C. P. & A. Photos)

(Left) Here is a modern Santa Claus and the very modern transmitting set through which he will speak to his legion of children this Christmas Eve. It is said that there are now over six million radio "listeners in" in the United States, and that nearly three million of them are children. So, this Christmas Eve, when dad begins his famous recitation, "Twas the Night Before," tell him not to be surprised if he is interrupted.

Page Kenneth F. Smith

EDITOR, RADIO WORLD:—I have a home-made receiving set, using a modified Colpitt's circuit with direct coupling and one Aeriotron (WD-11) vacuum tube operated on one dry-cell, with which I heard station KHJ, "The Times," Los Angeles, California, on two different occasions, namely: November 13 and 16. In addition to musical numbers, I heard two press messages broadcast by them which I understood very distinctly—one regarding the severe snow storms in the vicinity of Cheyenne, Wyoming, and the other regarding farm loans by Federal Reserve Banks. These facts may be verified. I figure Los Angeles a little over 2,000 miles from Cincinnati.

In addition to the above, I have heard PWX, Havana, Cuba, three times recently—a distance of over 1,450 miles, air-line; Denver, Colorado (DN-4), a distance of about 1,250 miles; and numerous other stations from 500 to 1,000 miles distant, such as Fort Worth and Dallas, Texas; Kansas City and Jefferson City, Missouri; Des Moines, Davenport, and Ames, Iowa; Minneapolis, Minnesota; Schenectady, Troy, and New York City, New York; Springfield and Bedford Hills, Massachusetts; Newark, New Jersey; Anacostia, D. C.; Atlanta, Georgia; and other nearby stations too numerous to mention.

I would not even intimate that this record has not been, or will not be, surpassed; but I think it is a fair record for a detector-tube set with *no stages of amplification*, using so little voltage. I would like to call the attention of Mr. Kenneth F. Smith, Birmingham, Alabama, to this letter, as he claims a record of 1,667 miles and says, "Come on, you amateurs; step up and get your feet wet!" I say, "Come on in, the water's fine!"

I will be glad to furnish the hook-up I am using, upon request.—F. E. Smith, 3508 Evanston Avenue, Cincinnati, Ohio.

Claims a Canadian Record

EDITOR, RADIO WORLD: The only radio magazine that I can get really interested in is RADIO WORLD. While reading your last issue I discovered that many of your readers have established, or are trying to establish, long-distance records with bulb sets. I am not in the habit of bragging, but I think I have established the long-distance record in Canada so far as crystal sets are concerned.

With an ordinary crystal receiver (not a loose-coupler) and a four-strand inverted-L type aerial I have been successful in hearing WWJ, Detroit "News"; WCX, Detroit, Michigan; WWI, Dearborn, Michigan; WJAX, Cleveland; KDKA, Pittsburgh; WGY, Schenectady, New York. I have heard all these stations regularly. I have also heard WOC, Davenport, Iowa.

Of course, I heard all these stations in the fall, when weather conditions are ideal. Still I would like to hear from any other crystal-set owner who has made a record.—W. M. Guillot, Box 224, Windsor, Ontario, Canada.

In 18 Days

EDITOR, RADIO WORLD:—I am sending a "DX night owl's" list. I have heard on my home-made one-tube, U-V 200 hook-up, by Greene, published in the Boston "Globe," October 15, the follow-

The Editors of RADIO WORLD will be pleased to receive sketches of hook-ups of the various "DX Night Owls" sending in records, with a view of publishing them.

Other letters from the DX "bugs" will be published from week to week.—The Editor.

ing stations in eighteen days, some of them more than once. My aerial is 42 feet high, 110 feet long, 2 wires, 4 feet apart, running east and west, T type:

KYW, WKN, WIAO, WBZ, WGY, WHAZ, KDKA, WIP, W2NA, WEAN, WJZ, WLK, WHAN, WLW, WBT, WOO, WNAC, WOC, WGM, WBU, WMAQ, WSB, WAAF, WDAF, WFAS, 2XI, WFI, WJAX, WOR, WAKP, WHAS, WEA, 1OMB, WJAR, NOF, 1OMK, WHA, WWJ.—William J. Head, Receiving Station WJH, 24 First Street, Bristol, Rhode Island.

* * *

"Get Your Feet Wet!"

EDITOR, RADIO WORLD: In RADIO WORLD, No. 35, dated November 25, a letter was printed concerning DX work.

The author of this particular letter is Kenneth F. Smith, 133 Francis Street, Birmingham, Alabama. Mr. Smith challenged amateurs to "step up and get their feet wet." I am here with a record which, I believe, will prevent me from getting my feet wet. I beg to submit the following record for one evening: All stations were heard on a one-step, using a Reinartz circuit. My aerial was 100 feet in length, 50 feet high, using a water pipe as a ground.

One evening I heard the following stations, all over 500 miles away: KHJ, Los Angeles, 1,535 miles; KHQ, Seattle, 1,740 miles, DN-4 and KFAF, Denver, 800 miles; WFAA and WBAP, Dallas and Fort Worth, both 750 miles distant; WNAC, Boston, 912 miles; WGM, WSB and WDAJ, all in or near Atlanta, 650 miles.

The following evening I heard KHJ, CKCK, Regina, Canada, 950 miles; WAAC, New Orleans, 830 miles; WIP, Philadelphia, 740 miles; also WBAP, WFAA, WGAG, WHB, and twenty others, all over 250 miles away.

Come on, you amateurs, and "get your feet wet!"

I would appreciate hearing from any other amateur not using radio-frequency who can equal the above record.—Howard J. Hall, 521 E. McKenney Street, Dixon, Illinois.

* * *

70 Ft. Long, 65 Ft. High

EDITOR, RADIO WORLD:—The record I have established with my set, I think, compares favorably with any I have read in your magazine. I use only a single-circuit regenerative set without any radio- or audio-frequency amplification whatsoever and only one tube. Yet I hear such stations as Minneapolis; WWJ, Detroit "News"; WOC, Davenport; Fort Dodge; WLW, Cincinnati; Cleveland; Chicago; WEA, New York (1322 miles, air-line); KDKA, Pittsburgh; Louisville; KSD, St. Louis; PWX, Havana; WSB, WGM, WDAJ, Georgia; Charlotte, North Carolina; Des Moines, Iowa; WEAV, Lincoln, Nebraska; WFAT, Sioux Falls, South Dakota; Portland, Oregon (2,127 miles, air-line); KHJ, Los Angeles (1,667 miles, air-line), and many other stations located within a radius of 500 miles such as Sweeney Auto

School; WHB, Jefferson City, Missouri; Denver, Colorado; and others. I use a double-strand aerial 70 feet long and 65 feet high. My set is home-made and is only a week old. The joints are not soldered yet. Furthermore, this is the first set I have ever owned or operated.—R. Diamond, 413 Royal Street, New Orleans, Louisiana.

* * *

Detector and 2-Stage

EDITOR, RADIO WORLD:—For some time I have taken a great interest in RADIO WORLD and thought I would send you the results I get with my home-made set—detector and two-stage audio. With this set and horn, which is a plain horn with receiver from head-set, I have heard the distant station of Honolulu and several others on the Pacific Coast; also many other stations in the United States and Canada. The hook-up is my own regenerative type.—Carlton D. Shults, Fort Plain, New York.

* * *

First Set in His Town

EDITOR, RADIO WORLD:—In RADIO WORLD, No. 31, dated October 28, Mr. J. A. Merklein, Brooklyn, New York, claims the receiving record, so I will send in the list of stations that I received on November 20:

WEAY, Houston, Texas; WGM, Atlanta, Georgia; WDAF, Kansas City, Missouri; WMAM, Beaumont, Texas; WHB, Kansas City, Missouri; WBAP, Fort Worth, Texas; WHAS, Louisville, Kentucky; WSB, Atlanta, Georgia; WOC, Davenport, Iowa; WWJ, Detroit, Michigan; WJAD, Waco, Texas; WOS, Jefferson City, Missouri; WHAN, Wichita, Kansas; WOI, Ames, Iowa; WCX, Detroit, Michigan; KSD, St. Louis, Missouri; WBZ, Springfield, Massachusetts.

All the concerts came in clear and loud, although I am only using one stage of amplification. I built my own set on June 4. There are only two sets in this town, mine being the first. Anyone desiring the hook-up I use, please write me. Best 73.—Quentin Weaver, Saratoga, Texas.

* * *

With Only One Bulb

EDITOR, RADIO WORLD:—Using only one bulb, I have heard over 60 different phone stations since June, scattered between the Pacific Coast, Canada, and Cuba, practically every high-powered station in the East, and a score or more of the low-powered ones are heard very QSA at all times. Reception from the South and West seems to be excellent. The most distant point in the West heard was KGW, Portland, Oregon, on July 8.—Albert Bannister, 2 Washington Street, Hudson Falls, New York.

* * *

On a Home-Made Set

EDITOR, RADIO WORLD:—I thought you would be interested to know that on Sunday evening, November 12, I received very clearly part of the program of WOC, Davenport, Iowa, on my home-made set which is only a single detector-bulb regenerative set. I used a Meteor Antenna Plug instead of outside antenna. If you care to check up this statement, at 10 p. m. eastern standard time, WOC was sending "The Star-Spangled Banner" played by the P. S. C. orchestra.—William C. Hicks, Waterford, New York.

What I Accomplish with My Home-made Set

By Paul G. Watson
3 BV, West Chester, Pennsylvania

Very neat, attractive and businesslike is the layout of Mr. Watson's set.

STATION 3 BV has made notable long-distance receiving records. On June 1, the C-W station 6 XAD, Avalon, California, was copied and confirmed by letter. C-W station 5 XA also comes in very QSA. The station signing 3 BV on C-W is Canadian 3 BV and may be distinguished from the United States stations as he uses "FM" instead of "DE" in calling and signing off.

All the apparatus is home-made from original designs. For the information of those interested in construction, the circuit of the short-wave tuner accompanies this article. It consists of a 43-plate .001 microfarad condenser, short-wave coupler, and two variometers. The pri-

cessfully. Phones, Magnavox, and small horn are connected to this amplifier—the small horn for sound reading of telegraph signals, the Magnavox for music, and the headset for DX signals. Music from many distant music stations have been received, WOC, WHB, WSB, WBAP and many nearby stations.

The transmitter is a low-power, coil affair, and does not use the rotary gap. Power has not been available for some time, hence the spark coil. However, tuned sharply to 190 meters, I have worked 44 miles. It is inductively coupled and radiates about three-tenths of an ampere.

The antenna is a 6-wire, inverted-L, 90 feet long with an average height of 45 feet. The ground system is a grid of wires buried under the antenna.

In the construction and design of this apparatus, many points of electrical design were considered. The wire used on all the pieces of the set is No. 14, and connections on the table were made with No. 10 wire. Care in insulating connecting wires, proper arrangement of apparatus, all contributed to the efficiency of this station

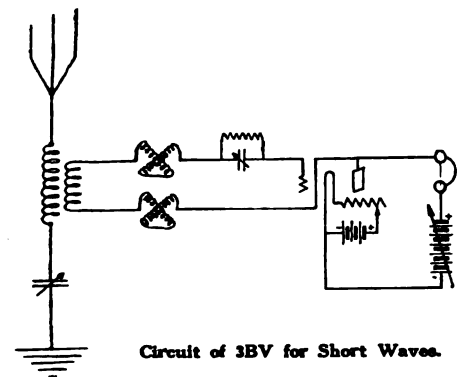

The above article and illustrations were contributed by Mr. Watson in response to RADIO WORLD'S call to amateurs and fans to send us just such material that brother radioists may profit by what others are doing. This is an ideal little story—brief, practical, and informative—and the accompanying photograph and hook-up complete it and give a capital idea of the author's very attractive set.—The Editors.

Battery Hints

KEEP your eye on your storage batteries. Don't let them stand too long without recharging.

If you charge them at home, take them to the service station at least once every year. A few dollars spent in having an expert look them over may save the price of a new battery.

Keep the tops of the elements covered at all times. The water evaporates, but the acid does not. Use only distilled water.

Circuit of 3BV for Short Waves.

mary inductance-switch of the variocoupler is back mounted and is controlled with a panel knob. Fine regeneration is obtained in this type tuner. The long-wave tuner is a honeycomb-coil tuner using a feed-back, or tickler, circuit. Either of these tuners may be connected to the audion-control panel through an anticapacity switch. This audion panel contains all the necessary controls, variable grid-condenser, vernier rheostat and B-battery switch for the "soft" tube. A two-step audio-frequency amplifier is connected to this detector. Acme A-2 transformers are used suc-

Latest Radio Patents

To Determine the Direction of Remote Radio Waves

No. 1,435,941. Patented: November 21, 1922. Patentee: James Robinson, Andover, England

MR. ROBINSON'S invention relates to improvements in electromagnetic arrangements for the reception of wireless waves, in which the direction of arrival of such waves from some remote point may be determined.

It is known that when an electrical circuit having characteristics suitable for the reception of electromagnetic waves is arranged in the form of a closed coil, or loop, the intensity of the signals received upon it from a remote transmitting station will be at a maximum when the plane of the coil coincides with the direction of propagation, or arrival, of the waves; and at a minimum when the coil is at right angles to the incoming waves. By rotating such a coil about an axis, it will be possible to discover the bearing of the transmitting station.

Mr. Robinson uses a pair of aerial coils in vertical planes set at an angle to each other—preferably at a right angle—and rotated about a vertical axis until no appreciable difference in strength of signal is found, when the effect of that coil which lies at right angles to the direction of arrival of the waves (the bearing of which is desired) is superimposed positively or negatively upon the effect of the other coil. Obviously the bearing can

Fig. 8
Eighth Figure of Mr. Robinson's patent showing diagrammatically a method of fitting coils to aircraft.

then be determined by the position of the first coil.

In the case of coils actually at right angles, the position for the reception of maximum signals by one coil can be roughly determined. By the superimposition of the other coil, this maximum position can be definitely fixed.

Not only does this arrangement represent a considerable saving of time in the determination of a bearing but it is now possible to appreciate and interpret signals, simultaneously and without interruption while their direction is being determined.

Holder for Hard Usage

No. 1,432,992. Patented, October 24, 1922. Patentee: John O. Gargan, Brooklyn, N. Y.

THIS invention relates to socket structures, and has for its object the provision of a socket in which spare vacuum tubes used in telegraph sets may be carried without undue vibration or liability to breakage.

In telegraph sending and receiving sets, particularly of the portable type for field work, it is often advisable to carry spare tubes. Due to the rough usage to which these sets are often subject it is necessary to provide a holder for them, of such construction that the tube shall not fall out.

Mr. Gargan's invention comprises a socket into which the tube is inserted and to which it is locked by a bayonet slot-construction acting in combination with a resilient means at the base of the socket which operates on the base of the tube to hold it in place.

The upper sketch is an elevation of the tube and socket, with a portion of the base broken away, showing the device attached to a portable telegraph set.

At right is a plan view looking downward on the device with tube removed from socket.

Broadcasting Gain for November Is 17 Stations

DURING November, the Department of Commerce licensed 46 broadcasting stations and cancelled 29. Three of those deleted were transferred to other ownership and have been recorded as new stations. The gain for the month was 17 stations, which indicates that the looked-for saturation point in broadcasting stations has not yet been reached.

The stations whose licenses were cancelled in November follow:

WLAT—Chas. G. Bosch Co., Burlington, Iowa.

WBAE—Bradley Polytechnic Institute, Peoria, Illinois.

WEAP—Brown's Business College, Peoria, Illinois.

WIAN—Chronicle & News Publishing Co., Allentown, Pennsylvania.

KFAV—Cooke & Chapman, Venice, California.

KDZJ—Excelsior Radio Co., Eugene, Oregon.

WKAJ—Fargo Plumbing & Heating Co., Fargo, North Dakota.

WKAT—Frankfort Morning Times, Frankfort, Indiana.

WDAW—Georgia Railway & Power Co., Atlanta, Georgia.

WGAF—Goller Radio Service, Tulsa, Oklahoma.

KDYN—Great Western Radio Corporation, Redwood City, California.

WBAQ—Myron L. Harmon, South Bend, Indiana.

KDYU—Herald Publishing Co., Klamath Falls, Oregon.

WFAL—Houston Chronicle Publishing Co., Houston, Texas.

WSV—Dr. L. M. Hunter and G. L. Carington, Little Rock, Arkansas.

WHAL—Jeffrey & Derby, Lansing, Mich. (now "Lansing Capitol News").

WFAX—Arthur L. Kent, Binghamton, New York.

KHJ—G. R. Kierulff & Co., Los Angeles, California.

WMAU—Louisiana State Fair Association, Shreveport, Louisiana.

WIAG—Matthews Electric Supply Co., Birmingham, Alabama.

KFDB—John D. McKee, San Francisco.

KDZD—W. R. Mitchell, Los Angeles.

Wouldn't It Be Great, If—

The fellow with the phone set on the next block, who radiates 'steen amps, wouldn't turn on full power when he talks to the fellow two blocks away?

• • •

Every time you have a bunch of people for company your set would work as well as it does just after they go home?

• • •

You could get the results out of your set that you tell the other hams you do?

the standardization of a high-precision standard wave meter by this means. A tuning fork of known frequency, approximately 1,000 cycles per second, is used as the basis of the standardization. A low-frequency generator is tuned to successive multiples of this frequency by means of the cathode-ray oscillograph, and corresponding settings of the wave meter are obtained. A third generator is similarly tuned to multiples of these frequencies, and thus by successive stages the standardization is extended to include frequencies as high as 5,000 kilocycles (60 meters). It is intended that this wave meter be used as the basic standard for the standardization of commercial wave meters.

Lighthouse Men Organize

SEVERAL men in the Lighthouse Bureau, Washington, D. C., have been dabbling with radiotelephone receiving sets, and it has occurred to them that their experience would be valuable to keepers and other members of the service who would like to enjoy the pleasures of the radio concerts. Therefore, they propose to organize a radio club among the amateur fans of the service. The initiation fee will be a postal, or letter, stating approval of the scheme and a desire to be enrolled as a member. The dues will be a word or two from time to time telling of difficulties encountered, results secured, or asking information. A space in the Lighthouse Service Bulletin will be reserved for answers to questions and interesting information that will enable them to construct their own sets or improve those they already own; also to conduct a clearing house for new ideas. Articles will appear from time to time on different phases of the subject. Charles C. Brush is in charge of the plan.

Basis of Radio Measurements

Bureau of Standards Develops Precise Method of Standardizing Wave-Lengths and Frequencies

THE Bureau of Standards has developed a very precise method of standardization of radio wave-lengths and frequencies, which is the fundamental basis of radio measurements in this country. By the process used, the frequency of radio waves is compared with that of an audible musical note. A tuning fork is mounted in such a way that it may be made to control the frequency of an oscillatory circuit. The frequency of another oscillatory circuit operating at much higher frequencies is then compared with it by an oscillograph.

This latter instrument consists of the cathode-ray tube—a special kind of vacuum tube in which the narrow stream of electrons is subjected to the action of electric fields applied by the two alternating-current generators. When neither generator is operating, the electron's, impinging on the active screen at the end of the tube, cause a single luminous spot. If one generator is connected, the spot is deflected back and forth along the single line, horizontal or vertical, as the case may be, with such rapidity that it appears as a solid line. If both generators are applied simultaneously, the spot oscillates both horizontally and vertically, and appears, in general, as a blurred luminous rectangle. If, however, the frequencies of the two generators bear a simple ratio, such as four to one, the spot traverses and retraverses a definite simple path, forming a figure by which the frequency ratio may be recognized. It has been found possible to compare frequency ratios as high as 21 to 1. The bureau is at present engaged in

RADIO FINDS A BETTER CONDENSER

Bayley's 25-.0005 and 43 Plate .0011. Its plates spaced close give it the finest tuning qualities. It is a die-cast product; the stationary plates are cast solid, accurately and permanently spaced, on three upright supports, while the movable plates are cast on the center revolving spindle. Plates cannot loosen, which eliminates shoring. Each condenser has our money-back guarantee.

Bank Operates Giant Radio

San Francisco Institution Broadcasts News to Fans West of Rocky Mountains

THE most powerful radio broadcasting-station on the Pacific Coast—and one of the most powerful in the United States—is now "on the air" in regular service on Telegraph Hill, San Francisco.

The station, officially known as KFDB, was established by the Mercantile Trust Company of California, and is the first on the Pacific Coast to be built, owned, and operated by a bank.

KFDB has a sufficient range to reach all points west of the Rocky Mountains. It is broadcasting every day (Sunday excepted) commercial, financial, and agricultural information between the hours of 10 and 11 a. m., and 2 to 3 p. m., with a musical program between 9 and 10 p. m.

The first attempt at broadcasting from KFDB, in August, developed an interesting

New Firms and Corporations

(The firms and corporations mentioned in these columns can be reached by communicating with the attorneys, whose addresses are given whenever possible.)

Benjamin Electrical Supply Co., Manhattan, \$10,000; B. Schmones, J. Solomon, D. Getz. (Attorney, M. S. Yochelson, 320 Broadway, New York.)

problem in radio engineering. The power was supplied direct from a 2,000-volt generator, but the commutator hum of the generator prevented satisfactory radio reception.

To eliminate this disturbing noise, it was decided to install a 2,000-volt 20 ampere-hour storage battery, and use the generator for recharging the battery in series. The Philadelphia Storage Battery Company supplied 333 Philco Radio A Batteries for the purpose, and regular broadcasting was started on November 1.

PERMANENT RADIO FAIR FOR BUYERS, Hotel Imperial, New York City. Open from September, 1922, to May, 1923.

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, December 21 to 31. Colwell & Korbell, Fisk Building, New York City, directors of publicity.

SECOND DISTRICT RADIO CONVENTION, Hotel Pennsylvania, New York City, March 1, 2, and 3, 1923.

FIRST UNIVERSAL EXPOSITION OF INVENTIONS AND PATENTS, Grand Central Palace, New York City, February 17 to 22, inclusive, 1923.

A Freshman Improvement

THE very latest improvement in radio is a combination variable grid-leak and Micon-condenser.

The grid-leak consists of a piece of fiber specially treated on which a bronze spring is rotated to vary the resistance in an unbroken range, from practically zero to five megohms. The condenser is a tested Micon-condenser of .00025 mfd. The whole is combined and sealed in a neat molded body with nicked binding-posts and a pointer and dial to set the grid-leak resistance.

Every tube requires a different grid-leak resistance to operate at its maximum efficiency, especially when working on weak signals. It has been found in practice that it is possible to tune in distant stations by varying the grid-leak resistance to the proper point.

The variable grid-leak and condenser may be used in the parts of the circuit to eliminate noise and distortion. It has distinct advantage when placed across phones instead of usual phone condensers.

This device is manufactured by the Chas. Freshman Company, Inc., of New York City. The accuracy and construction will be in line with the tested Micon-condenser now well known in the radio field.

Improved Anti-Capacity Radio Jacks

Manufactured by the Radio Improvement Co., 25 West 43rd Street, New York City

THE improved Anti-Capacity Radio Jack is one of the latest developments in radio and was designed especially for radio work. Radio enthusiasts are quick to realize the importance of these jacks—no soldering of wires, an important element; occupies less room, which is very true; inductance is practically eliminated and it has a classy appearance. This device is practically an improved radio jack, radically different from all styles of the old ordinary telephone jack. They will fit any plug. Owing to the elimination of long leads, induction is minimized. They are made in single circuit, open; single circuit, closed; double circuit, closed; and both single and double filament circuit. The "A" Battery Switch is, also, a practical device which, due to its red knob, permits the "A" Battery to be disconnected or connected at a pull, or push, of a knob.

28	252	504	1008	1512	2023
29	328	656	1312	1968	2625
30	416	832	1664	2496	3335
31	477	954	1908	2862	3820
32	609	1228	2436	3654	4876
33	770	1540	3080	4620	6243
34	969	1938	3876	5814	7757
35	1207	2414	4828	7242	9660
36	1488	2976	5952	8828	11967
37	1684	3368	6735	10104	13474
38	2064	4128	8256	12384	16516
39	2782	5564	11128	16592	22261
40	3368	6736	13472	20208	26947

The following tables have already been published:

- No. 1—Enameled Magnet Wire, RADIO WORLD, No. 34, dated November 18.
- No. 2—Single Cotton-Covered Wire, RADIO WORLD, No. 35, dated November 25.
- No. 3—Double Cotton-Covered Wire, RADIO WORLD, No. 36, dated December 2.

American Radio Exposition Offers Prizes to Boys and Girls

IN order to stimulate interest in the wonders of radio among school boys and girls, prizes aggregating \$200 in gold and a few additional prizes other than cash are being offered by the management of the American Radio Exposition at the Grand Central Palace, December 21 to 30.

To the boy or girl in school or high school who enters in the contest the most ingenious home-assembled set of radio apparatus, a prize of \$100 in gold will be awarded. The second prize will be \$50 in gold; third prize, \$25; fourth prize, \$15; fifth prize, \$10. There will be also several other prizes worth competing for, including ten tickets of admission to the exposition for sixth prize; eight tickets for seventh prize, and six tickets for eighth prize.

To be eligible, contestants must be bona fide amateurs and bring their entry to the exposition to be exhibited. The parts may be home made or assembled and the ingenuity and original ideas embodied in such assembly will count as the chief factor. An inexpensive layout will have just as much chance of winning first prize as an expensive one.

Pupils of public schools, high schools and private schools within a radius of one hundred miles will be eligible. Special prizes for amateurs under twenty-one years of age, who are no longer in school, will be offered.

Prospective contestants must make their entry by letter (not in person) to the American Radio Exposition, 120 Broadway, New York, on or before Saturday, December 16, and they will receive particulars relative to exhibiting the apparatus. The management reserves the right to exhibit or not to exhibit any entries. A jury of competent impartial engineers in no way connected with the management of the Exposition will make the awards.

"The Fool" Broadcast

First Theatrical Performance to Be Sent by Radio from Stage
